16. Abstract (Limit: 200 words)

This report, one of a series of reports concerning exposure assessment, describes methods for estimating the sizes of populations potentially exposed to chemical substances. Five categories of exposed populations are covered: (1) populations exposed to chemicals in the ambient environment, (2) workers, (3) populations exposed through ingestion of chemicals in food, (4) users of consumer products, and (5) populations exposed through ingesting chemicals in drinking water. The report contains general data on populations from governmental agencies such as the U.S. Bureau of Census, U.S. Department of Labor, U.S. Department of Agriculture, and EPA's Office of Drinking Water. It also contains step-by-step methods for locating and using data to enumerate each subpopulation identified as potentially exposed to toxic chemicals. Appendix A contains sample calculations illustrating the methods presented in the text. Appendix B is OSHA's Industry-Occupation (I-O) Matrix, described in Section 3 of the report.

FOREWORD

This document is one of a series of volumes, developed for the U.S. Environmental Protection Agency (EPA), Office of Toxic Substances (OTS), that provides methods and information useful for assessing exposure to chemical substances. The methods described in these volumes have been identified by EPA-OTS as having utility in exposure assessments on existing and new chemicals in the OTS program. These methods are not necessarily the only methods used by OTS, because the state-of-the-art in exposure assessment is changing rapidly, as is the availability of methods and tools. There is no single correct approach to performing an exposure assessment, and the methods in these volumes are accordingly discussed only as options to be considered, rather than as rigid procedures.

Perhaps more important than the optional methods presented in these volumes is the general information catalogued. These documents contain a great deal of non-chemical-specific data which can be used for many types of exposure assessments. This information is presented along with the methods in individual volumes and appendices. As a set, these volumes should be thought of as a catalog of information useful in exposure assessment, and not as a "how-to" cookbook on the subject.

The definition, background, and discussion of planning exposure assessments are discussed in the introductory volume of the series (Volume 1). Each subsequent volume addresses only one general exposure setting. Consult Volume 1 for guidance on the proper use and interrelations of the various volumes and on the planning and integration of an entire assessment.

The titles of the nine basic volumes are as follows:

Volume 1	Methods for Assessing Exposure to Chemical Substances (EPA 560/5-85-001)
Volume 2	Methods for Assessing Exposure to Chemical Substances in the Ambient Environment (EPA 560/5-85-002)
Volume 3	Methods for Assessing Exposure from Disposal of Chemical Substances (EPA 560/5-85-003)
Volume 4	Methods for Enumerating and Characterizing Populations Exposed to Chemical Substances (EPA 560/5-85-004)
Volume 5	Methods for Assessing Exposure to Chemical Substances in Drinking Water (EPA 560/5-85-005)

Preceding page blank

Volume 6	Methods for Assessing Occupational Exposure to Chemical Substances (EPA 560/5-85-006)
Volume 7	Methods for Assessing Consumer Exposure to Chemical Substances (EPA 560/5-85-007)
Volume 8	Methods for Assessing Environmental Pathways of Food Contamination (EPA 560/5-85-008)
Volume 9	Methods for Assessing Exposure to Chemical Substances Resulting from Transportation-Related Spills (EPA 560/5-85-009)

Because exposure assessment is a rapidly developing field, its methods and analytical tools are quite dynamic. EPA-OTS intends to issue periodic supplements for Volumes 2 through 9 to describe significant improvements and updates for the existing information, as well as adding short monographs to the series on specific areas of interest. The first four of these monographs are as follows:

Volume 10	Methods for Estimating Uncertainties in Exposure Assessments (EPA 560/5-85-014)
Volume 11	Methods for Estimating the Migration of Chemical Substances from Solid Matrices (EPA 560/5-85-015)
Volume 12	Methods for Estimating the Concentration of Chemical Substances in Indoor Air (EPA 560/5-85-016)
Volume 13	Methods for Estimating Retention of Liquids on Hands (EPA 560/5-85-017)

1. INTRODUCTION

This volume is the fourth in a series of nine volumes presenting methods for assessing exposures to chemical substances; the reports are being developed for the U.S. Environmental Protection Agency (EPA), Office of Toxic Substances (OTS). This volume presents methods and supporting information for enumerating and characterizing populations exposed to chemical substances in each of the EPA-OTS defined exposure categories. The purpose and scope of this report, the report organization, and the methodological framework are discussed in the following subsections.

1.1 Purpose and Scope

This document and the methods that it contains have been prepared to aid in overcoming one of the major difficulties encountered in the preparation of exposure assessments for individual chemical substances: the enumeration and characterization of specific populations exposed to chemical substances. Each of the seven categories of an exposure assessment has certain populations associated with it, and each population has further subpopulations that vary with respect to the concentrations to which they are exposed and the frequency and duration of exposure. While it has often been possible to identify exposed populations from monitoring or release data, it has rarely been possible to estimate sizes of specific subpopulations. The purpose of this report, therefore, is to catalog pertinent information, data bases, and tools, and to provide a systematic approach or methods whereby the population exposed to a given chemical substance in each of the exposure categories can be enumerated and characterized according to age and sex at any desired level of detail.

1.2 Report Organization

The data sources and methods to enumerate and characterize exposed populations in each of the exposure categories are specific to that exposure category. This report, therefore, is divided into separate sections according to the category of exposed populations as follows:

- Section 2 - Populations Exposed to Chemical Substances in the Ambient Environment
- Section 3 - Populations Exposed to Chemical Substances in the Occupational Environment
- Section 4 - Populations Exposed to Chemical Substances via the Ingestion of Food

- Section 5 - Populations Exposed to Chemical Substances via the Use of Consumer Products
- Section 6 - Populations Exposed to Chemical Substances via the Ingestion of Drinking Water.

Exposures resulting from the disposal and transportation related spills of chemical substances are subsets of exposures occurring in the ambient environment. Populations exposed to chemical substances in these categories are identified either geographically or by occupation. Section 2 of this report covers the geographic enumeration and characterization of exposed populations, while Section 3 covers the enumeration and characterization of occupationally exposed populations. Finally, demonstrations of the methods contained in each section of this report are presented as example population problems in the Appendix.

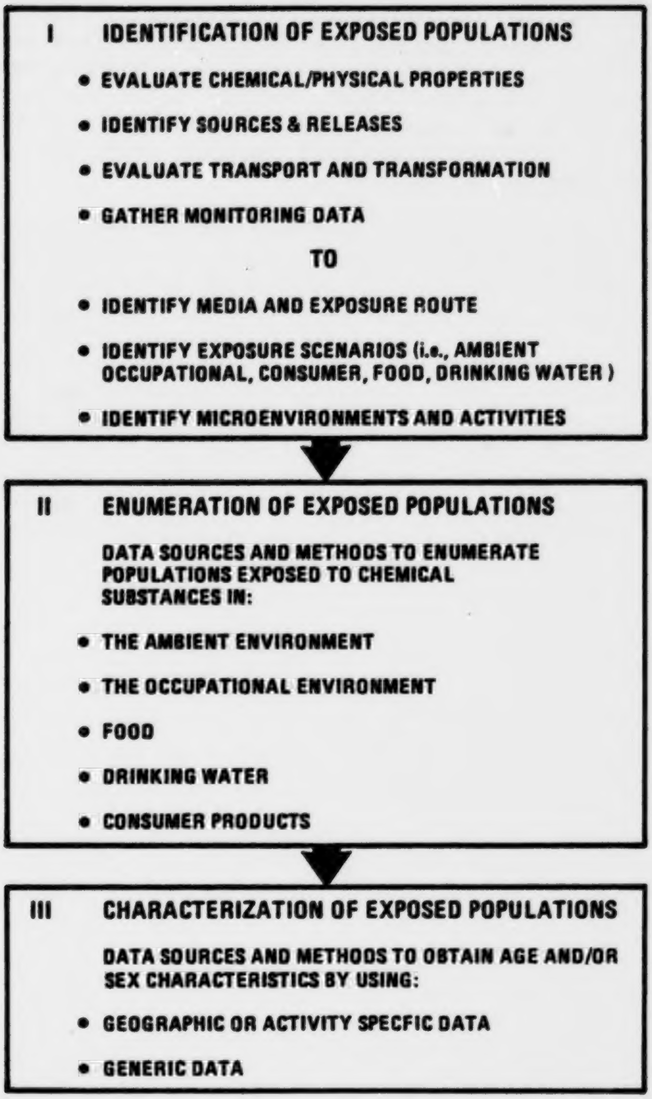
1.3 Framework of Methods

The framework for enumerating and characterizing exposed populations is the same for each of the sections and comprises three stages. These stages are:

1. The identification of the exposed population.
2. The enumeration of the exposed population.
3. The characterization of the exposed population according to age and sex.

Figure 1 is a flow diagram of the three-stage framework. The following paragraphs briefly describe each stage; detailed information is provided in each of the sections of this report.

The first stage, the identification of exposed populations, is a function of the chemical and physical properties, sources of environmental release (i.e., manufacturing, processing, distribution, use, and disposal), and environmental transport and transformation of a chemical substance. Identification and evaluation of these data will indicate the media (i.e., air, water, soil), exposure route (inhalation, ingestion, dermal absorption), exposure category or scenario (e.g., ambient, occupational, drinking water), and the activities that lead to exposure or the microenvironments where exposure occurs. Information on identifying exposed populations is contained in Volumes 2 through 9 of this exposure assessment methods report series.. This report only briefly describes the procedures for identifying exposed populations.



I IDENTIFICATION OF EXPOSED POPULATIONS
• EVALUATE CHEMICAL/PHYSICAL PROPERTIES
• IDENTIFY SOURCES & RELEASES
• EVALUATE TRANSPORT AND TRANSFORMATION
• GATHER MONITORING DATA
TO
• IDENTIFY MEDIA AND EXPOSURE ROUTE
• IDENTIFY EXPOSURE SCENARIOS (i.e., AMBIENT OCCUPATIONAL, CONSUMER, FOOD, DRINKING WATER)
• IDENTIFY MICROENVIRONMENTS AND ACTIVITIES
II ENUMERATION OF EXPOSED POPULATIONS
DATA SOURCES AND METHODS TO ENUMERATE POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES IN:
• THE AMBIENT ENVIRONMENT
• THE OCCUPATIONAL ENVIRONMENT
• FOOD
• DRINKING WATER
• CONSUMER PRODUCTS
III CHARACTERIZATION OF EXPOSED POPULATIONS
DATA SOURCES AND METHODS TO OBTAIN AGE AND/OR SEX CHARACTERISTICS BY USING:
• GEOGRAPHIC OR ACTIVITY SPECFIC DATA
• GENERIC DATA

Figure 1. Three-stage Framework for Identifying, Enumerating, and Characterizing Populations Exposed to Chemical Substances

The second stage involves the use of various data sources, computerized data bases, and generic information to enumerate exposed populations. In the appropriate exposure category sections of this report, data sources are discussed, including any limitations; the responsible agencies or individuals who must be contacted to obtain the required information are also listed. Methods utilizing the various data sources are presented in a step-by-step fashion in each section so that the investigator or exposure assessment team can enumerate exposed populations efficiently.

The final stage describes the data sources and procedures to be used to characterize the exposed population. Characterization of the exposed population involves determining the numbers of individuals in particular age and sex classes. The age and sex of the exposed population affect the physiological parameters that determine exposure (i.e., breathing rate, body weight, skin surface area) and identify sensitive subpopulations (e.g., children, women of childbearing age). Detailed exposure assessments may require that populations be described by age and sex distribution. The procedures presented for this stage in each of the exposure category sections direct the investigator or assessment team in the use of geographic data, activity-specific data, or generic data on age and sex distributions to characterize exposed populations.

2. POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES IN THE AMBIENT ENVIRONMENT

2.1 Introduction

This section presents methods for enumerating and characterizing populations exposed to chemical substances in the ambient environment. The methods described are applicable to populations exposed as a result of industrial effluents, non-point or area sources, natural sources, disposal related releases, consumer related releases, spills from transportation or storage activities, and unknown sources.

Figure 2 is a flow diagram of the three-stage framework for enumerating populations exposed to chemical substances in the ambient environment. Included in the diagram are some of the major data sources used in the three stages.

The identification of exposed populations is discussed only briefly in this section (Subsection 2.2); the ambient exposure assessment methods report (Volume 2) describes the process in detail.

The enumeration of the exposed population principally relies on population data collected by the Bureau of the Census, particularly the decennial Census of Population. The most recently conducted Census, the data publication form and document titles, and the use of census data in exposure assessment population studies are discussed in detail in Subsection 2.3.

The age and sex of the exposed population affect the physiological parameters that determine exposure (e.g., breathing rate, skin surface area) and identify sensitive subpopulations (e.g., women of child-bearing age, the elderly). Detailed exposure assessments may require that populations be described by age and sex distribution. Subsection 2.4 discusses the data sources and procedures to characterize populations by age and sex distribution.

2.2 Identification of Exposed Populations

Populations potentially exposed to a chemical substance in the ambient environment are identified through an evaluation of the substance's sources, its behavior in the environment, and applicable monitoring data. Subpopulations may be further defined by their participation in specific activities leading to exposure. Method 2-1 summarizes the steps involved in identifying populations exposed to chemical substances in the ambient environment. Volume 2 of this series describes the requisite data in detail.

Figure 2. Three-stage Framework for Enumerating and Characterizing Populations Exposed to Chemical Substances in the Ambient Environment

Method 2-1. General Procedure for Identifying Populations Exposed to Chemical Substances in the Ambient Environment

Step 1 Identify the locations of chemical release into the environment; define each release to the atmosphere as a point, area, or line source. Using monitoring data and/or environmental fate information, identify the geographic locales and media of concern (air, water, land). Volume 2 of this series catalogs data bases, information sources, and tools that will aid in this process.

Step 2 For each medium of interest, evaluate the significance of exposure routes:

- Air - inhalation
- Water - dermal contact
- Land - dermal contact

Step 3 Identify exposed populations by listing significant pathways:

- Persons breathing ambient air contaminated by atmospheric point, area, or line sources.
- Persons swimming in contaminated surface waters.
- Non-human populations of ecological or economic importance residing in the locale and media of concern.
- Other populations not specifically addressed in this volume (e.g., children swallowing or chewing objects or playing in soil contaminated with fallout of particulates consisting of or containing the chemical substance).

Exposed populations are initially identified as those near sources of the substance; modeling and monitoring provide the geographic definition of "near" by defining the levels of exposure in the environment at a given point or general location. Knowledge of a substance's physical and chemical properties, emission characteristics, and environmental transport and transformation helps to identify the physical state of the chemical and the media (e.g., air, water) into which it is released and to which it will partition. The physical state and media in turn determine the potential exposure routes: inhalation, ingestion, and dermal contact.

In order to enumerate exposed populations, identification must be refined beyond the determination of exposure route by considering the geographic locations where the chemical is released and the activities in the ambient environment that result in exposure. Inhalation exposures may result from proximity to:

- Point sources - known locations of emissions identifiable by geographic coordinates (e.g., industrial discharges, disposal sites).
- Area sources - sources related to chemical use or incidental emission defined by broad geographic boundaries (e.g., urban areas as a source of automotive exhaust).
- Line sources - sources of chemical emission, usually assumed to be at a constant rate, that are mobile and move along a pathway or line such as a road, rail, or river.

Since breathing is a constant activity, populations exposed via inhalation are defined only by the sources listed above.

Dermal exposure to a chemical substance may result from contact with ambient air, water, or soil. Dermal exposure to airborne contaminants is likely to be insignificant in comparison to inhalation exposure. The most important exposure pathways for the dermal route are probably swimming in surface waters and contacting soil during work or play.

Only the most significant and common pathways of exposure are considered in this report. There are numerous other exposure pathways in the ambient environment that are not dealt with in this report (e.g., ingestion of contaminated soil by children). Identification of these pathways and the exposed populations must be addressed within individual exposure assessments. The data bases, information sources, and tools discussed in this report will aid in this process.

2.3 Methods for the Enumeration of Exposed Populations

This section discusses the data sources and recommended procedures for enumerating populations exposed to chemical substances in the ambient environment. Because populations exposed to chemical substances in the ambient environment are defined geographically and since the Census of Population is the major geographic population data base, the first subsection (2.3.1) is devoted to its discussion. The methods developed for the enumeration of exposed populations are subsequently discussed according to inhalation exposure in Subsection 2.3.2 and dermal exposure in Subsection 2.3.3.

2.3.1 Census of Population

The U.S. Census, conducted once every decade, determines the size, distribution, and demographic characteristics of the population. The most recent Census was conducted in 1980 and is divided into two categories: (1) complete count data for the entire U.S. population (short form) and (2) more detailed population, social, and economic characteristics for 20 percent of the U.S. population (long form). The data collected in each of these categories are listed in Table 1.

The data collected in the Census are organized according to geographic areas in the U.S. as illustrated in Figure 3 and within geographic areas according to census-defined statistical areas and government units as listed in Table 2. Figure 4 illustrates the geographic organization of the major census statistical areas (i.e., Standard Metropolitan Statistical Areas (SMSAs), urbanized areas, and urban and rural areas). The detailed breakdown of census geography is illustrated in Figures 5 and 6. Population data, therefore, are available within SMSAs to the level of the Block and in non-SMSAs to the level of the Enumeration District (ED).

Census geography and the population data available for each geographic category are extremely important throughout this methodology. In this section, and all sections of the methodology, census geography will be used as consistently as possible. It should be noted that many organizations report population data according to what appears to be census geographic categories (e.g., "urban" population, "rural" population). Upon further investigation, however, sample design and data presentation may not strictly follow the census definition of geographic categories. When using population data not reported by the Bureau of the census, therefore, the investigator should carefully review the geographic categories of data presentation for consistency with the census classifications.

Table 1. Population Subject Items Included in the 1980 Census

100% Items	Sample items (20% sample or 1 out of 6 households)
• Household relationship	• School enrollment
• Sex	• Educational attainment
• Race	• State or foreign country of birth
• Age	• Citizenship and year of immigration
• Marital status	• Current language and English proficiency
• Spanish/Hispanic origin or descent	• Ancestry
	• Place of residence five years ago
	• Activity five years ago
	• Veteran status and period of service
	• Presence of disability or handicap
	• Children ever born
	• Marital history
	• Employment status last week
	• Place of work
	• Travel time to work
	• Means of transportation to work
	• Number of persons in carpool
	• Year last worked
	• Industry
	• Occupation
	• Type of employment
	• Number weeks worked in 1979
	• Usual hours worked per week in 1979
	• Number weeks looking for work in 1979
	• Amount of income in 1979 by source

Figure 3. Geographic Regions and Divisions of the United States

Table 2. Geographic Units of the Census of Population

Statistical areas

- Regions: Regions are large, geographically contiguous groups of states (with the exception of the region that includes Alaska and Hawaii). There are four regions: Northeast, North Central, South, and West (see Figure 1).

- Divisions: Divisions are groups of states which are subdivisions of regions. There are nine divisions: New England, Middle Atlantic, South Atlantic, East South Central, West South Central, East North Central, West North Central, Mountain, and Pacific (see Figure 1).

- Standard Metropolitan Statistical Areas (SMSAs): An SMSA is an integrated economic and social unit with a recognized large population nucleus. Generally, each SMSA consists of one or more entire counties, or county equivalents, that meet standards pertaining to population and metropolitan character. In New England, towns and cities, rather than counties, are used as the basic geographic units for defining SMSAs. In Alaska, census divisions are used to define SMSAs. Criteria used to delineate the 267 SMSAs for which data were tabulated for the 1972 Economic Censuses specified that an SMSA include at least (1) one city with 50,000 inhabitants, or more or (2) a city having a population of at least 25,000 which, with the addition of the population of contiguous places, incorporated or unincorporated, has a population density of at least 1,000 persons per square mile. Together, they must constitute, for general economic and social purposes, a single community with

Government units

- The United States

- States: The 50 states are the major political units of the United States. The District of Columbia is treated as a state-equivalent.

- Counties: Counties are the primary political and administrative divisions of the states.

- Minor Civil Divisions (MCDs): These are the primary political and administrative subdivisions of counties; most frequently known as townships, but in some states include towns, precincts, and magisterial districts.

- Census County Divisions (CCDs). In 21 states, MCDs were found to be unsuitable for presenting statistics due to area's small population size, frequent boundary changes, etc. CCDs are defined with boundaries that seldom change and can be easily located (e.g., roads, railroads, power lines, and bridges).

- Places: A concentration of population, regardless of the existence of legally prescribed units, powers, or functions. In the 1970 Census, most places are incorporated as cities, towns, villages, or boroughs.
  - Incorporated places: These are political units incorporated as cities, boroughs (excluding Alaska and New York), villages, and towns (excluding the New England States, New York, and Wisconsin). Most incorporated places are subdivisions of the MCD or CCD in which they are

Table 2. (continued)

Statistical areas	Government units
a combined population of at least 50,000, provided that the county or counties in which the city and contiguous places are located has a total population of at least 75,000. • Central cities (of an SMSA): The largest city of an SMSA is always a central city. One or two additional cities may be added to the SMSA title and identified as central cities if: (1) the additional city or cities have a population of one-third or more of that of the largest city and a minimum population of 25,000 or (2) the additional city has at least 250,000 inhabitants. • Standard Consolidated Statistical Areas (SCSAs): Two or more contiguous SMSAs which meet certain criteria of population size, urban character, social and economic integration, and contiguity of urbanized areas. Examples are: Detroit-Ann Arbor, MI, Seattle-Tacoma, WA, San Francisco-Oakland-San Jose, CA. • Urbanized Areas (UAs): Contain a central city (or twin cities) meeting the same criteria as an SMSA, plus the surrounding closely settled incorporated and unincorporated areas which meet certain criteria of population size or density. UAs differ from SMSAs chiefly by excluding the rural portions of counties that make up the SMSAs as well as those places that are separated by rural territory from the densely populated fringe around the central city.	located, for example, a village located within and legally part of a township. However, almost 4,000 incorporated places cross MCD and/or county lines, but no incorporated places cross state lines since they are chartered under the laws of a state. There were over 18,500 incorporated places in 1970. • Unincorporated places. These are densely settled population centers without legally defined corporate limits or any other corporate powers or functions. In 1970, statistics were tabulated for each unincorporated place with 5,000 inhabitants or more if located inside an urbanized area, or with 1,000 inhabitants or more if located outside an urbanized area.

Table 2. (continued)

Statistical areas	Government units
• Urban and Rural Areas: Urban population comprises all persons living in urbanized areas and in places of 2,500 inhabitants or more outside urbanized areas. The population not classified as urban constitutes the rural population. This is divided into rural-farm (all rural households living on farms) and rural nonfarm (remaining rural population).	
• Census Designated Place (CDP): for the 1980 Census, CDPs will be used to describe densely settled population centers without legally defined limits or corporate powers. CDPs, like unincorporated places in 1970, contain a dense, city-type street pattern and ideally should have an overall population density of at least 1,000 persons per square mile. In addition, a CDP should be a community that can be identified locally by place name, having developed over the years from a small commercial area or market center, rather than encompassing a residential land subdivision, apartment development, or general urban expansion area.	
• Census Tracts: Generally, small, relatively permanent areas into which metropolitan and certain other areas are divided. An average tract contains about 4,000 residents. All SMSAs are completely tracted.	
• Enumeration Districts (EDs): Areas within census tracts, MCDs, and CCDs with an average of about 800 people or 250 housing units. EDs are generally used when block groups are not defined for an area. Together with Block Groups, the ED/BG category covers the entire U.S.	

Table 2. (continued)

Statistical areas	Government units
• Block Groups (BGs): This area is a combination of contiguous blocks having an average population of about 1,100. BGs are subdivisions of census tracts.	
• Blocks: A census block is a well-defined piece of land, bounded by streets, roads, railroad tracks, streams, or other features on the ground. Blocks do not cross census tract boundaries, but may cross other boundaries such as city limits. Blocks are the smallest areas for which census data are tabulated.

Figure 6. Census Geography For Metropolitan and Nonmetropolitan Counties

The data collected in the 1980 Census of Population are in the process of being released by the Census Bureau. The data are available both in printed documents and on computer tape. Table 3 lists the printed documents that are or will be available in the near future from the Census Bureau.

The Number of Inhabitants (Series PC80-1-A) and General Population Characteristics (Series PC80-1-B) are the most useful reports for obtaining population data down to the town or township level. Both documents are available according to state, and each includes a separate U.S. summary document. Number of Inhabitants provides only population counts (i.e., no age and sex or other demographic data). General Population Characteristics provides population counts by sex and by age and sex as well as the other demographic data listed in Table 3 to the same geographic resolution as Number of Inhabitants.

Detailed counts and characteristics within Standard Metropolitan Statistical Areas (SMSAs) are available in Census Tracts (Series PHC80-2) and Block Statistics (PHC80-1). Census Tracts will be issued with accompanying maps (for tract identification) and will contain detailed characteristics of the population (e.g., age, sex, race, education).

Census Tracts is available by the photocopied page, and by mid-1983 it will be available on microfiche by SMSA (which is less expensive) and on computer tape. If further resolution or detail is required, Block Statistics may be consulted. This has been issued in microfiche only with accompanying maps both in print and on microfiche. Block Statistics provides population counts only; further information on population characteristics is not available on such a detailed level.

Detailed demographic information collected in the 20 percent sample Census (long form) is available in the series General Social and Economic Characteristics (PC80-1C) and Detailed Population Characteristics (PC80-1-D). General Social and Economic Characteristics provides demographic data to the town or township level of detail according to states. A U.S. summary report is also included in the series. Detailed Population Characteristics is available by state, U.S. summary, and SMSA. These two reports provide considerable information on the population characteristics previously listed in Table 1.

All of the information sources previously discussed contain results from the 1980 Census; they are available in most reference libraries. Specific population data that have been collected in 1980 and that have not yet been released may be obtained by calling the Population Division of the Bureau of the Census (202-763-5002 or 5020).

Table 3. Information on 1980 Census Reports: Their Geographical Breakdown, Characteristics, and Expected Dates of Release

Series	Name	Geographical breakdown	Characteristics	Expected dates of release
PC80-1-A (complete count data - 100%)	Number of inhabitants (U.S. Summary and by state)	United States Regions Divisions States SCSAs, SMSAs Urbanized areas Incorporated places Counties County subdivisions	Population counts	Available
PC80-1-B (complete count data - 100%)	General Population Characteristics (U.S. Summary and by state)	United States Regions Divisions States SCSAs, SMSAs Urbanized areas Places & towns/townships of 1,000 or more Counties Rural portion of counties	Population counts by sex	Available
		United States States SCSAs, SMSAs Urbanized areas Places & towns/townships of 10,000 to 50,000 Places & towns/townships of 2,500 to 10,000 Counties	Age and sex, household type & relationship, type of family, and marital status	

Table 3. (continued)

Series	Name	Geographical breakdown	Characteristics	Expected dates of release
PC80-1-C (sample estimate data - 20%)	General Social and Economic Characteristics (U.S. Summary and by state)	United States Regions Divisions States SCSAs, SMSAs Urbanized areas Place & towns/ townships of 50,000 or more Places & towns/ townships of 2,500 to 10,000 counties	Population counts	Mid to late 1983
		United States States Counties	Population counts for non-rural and rural farms.	
		United States States	Age & sex, fertility, household relationship, education, family composition, nativity and place of birth, residence in 1975, journey to work, disability status, veteran status, labor force status, class of worker, industry and occupation, income and poverty status.	
		States SMSAs[d] Urbanized areas[d] Places & towns/ townships of 50,000 or more[d] Central cities[d] Places & towns/ townships of 10,000 to 50,000[d] Counties	Age & sex, fertility, household relationship, education, family composition, marital status, nativity & place of birth, residence in 1975, journey to work, disability status, type of group quarters, veteran status, labor force status, class of worker, industry & occupation, income & poverty status.	

Table 3. (continued)

Series	Name	Geographical breakdown	Characteristics	Expected dates of release
PC80-1-D (sample estimate data - 20%)	Detailed Population Characteristics (U.S. Summary and by state)	United States States SMSAs of 250,000 or more	Cross-tabulations of social & economic characteristics by age, sex, etc.	Mid to late 1983
		States SMSAs of 250,000 or more[e]	Social and economic characteristics	
PHC80-2 (sample estimate data - 20%)	Census Tracts[b] (U.S. Summary and by SMSA)	SMSAs Central cities Counties Places of 10,000 or more Census tracts	Population counts (number of people in each tract by SMSA & other tracted areas)	Late 1983 (currently available on a photocopy basis)
		SMSA[c] Counties[c] Places of 10,000 or more[c] Census tracts[c]	Age and sex, fertility, household relationship, education, family composition, marital status, nativity, language usage and ability to speak English, residence in 1975, journey to work, disability status, labor force status, industry and occupation, income and poverty status. Structural equipment, financial and household characteristics of housing units.	

Table 3. (continued)

Series	Name	Geographical breakdown	Characteristics	Expected dates of release
PH80-1 (complete count data - 100%)	Block Statistics[a] (microfiche only; maps printed - U.S. Summary and by SMSA)	States SMSAs Counties County Subdivisions Places Tracts Blocks	Population counts	Available

Note: Data for towns/townships are shown for 11 states only: Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Michigan, and Wisconsin.

[a] Report contains 100% data; race and Spanish origin data, where presented, are provisional.
[b] Report contains both 100% and sample data.
[c] Data are shown only for those groups having 400 or more persons in the specific geographic area.
[d] Data for American Indian, Eskimo, and Aleut and Asian and Pacific Islander are shown for the specific geographic area having 1,000 or more persons of the population group.
[e] Data are shown only for those groups having 25,000 or more persons in the specific geographic area.

Source: Bureau of the Census, Customer Services Branch; Washington, D.C. (202-763-4100).

Another source of census information is the computerized Summary Tape Files (STFs). There are five basic files. STFs 1 and 2 are derived from the complete-count part of the Census and reflect respondents' answers to questions on the short form. STFs 3, 4, and 5 contain estimates derived from the sample part of the Census (20 percent sample) and cover the full range of topics represented on the long form. Although the source of information is the same, the STFs are designed to provide much greater geographic and subject detail (e.g., age, sex, education, marital status) than is feasible or desirable in printed reports. The STFs are only on magnetic computer tape, with the exception of STF 1A, which is also available on microfiche. Each of the five STFs is divided into Parts A, B, and C. Table 4 illustrates the relationships between the 1980 printed reports and STFs 1 through 5. Table 5 illustrates the geography of each file and its three parts. Table 6 lists the geographical resolution that will appear on the 1980 STFs, as well as the tentative schedule of release for these files.

Several other types of computer tape files are also available for population data (Bureau of the Census 1982a). Of particular importance is the Master Area Reference File (MARF). MARF contains numeric codes and names of all geographic areas used in the 1980 Census. The file also contains population and housing data for each area in the file. Donnelly Marketing, Incorporated, a subsidiary of Control Data Corporation, has acquired the file and added geographic coordinates (latitude-longitude) to all ED/BGs in MARF. This permits computerized mapping of the population data. This file along with the proprietary geographic coordinate data was recently purchased by EPA-OTS and entered into its Graphical Exposure Modeling System (GEMS). EPA-OTS can now access, aggregate, and manipulate 1980 population data as well as display the geographic distribution of the data in conjunction with ambient concentration data predicted by fate models. Details on MARF and its application as well as GEMS and the computerized concentration prediction models are discussed in the next subsection.

The STFs and other computer tape files such as MARF are considerably more expensive than printed reports. One STF reel (approximately one state) costs $140 compared to $5 for comparable printed reports. Computer tape files, however, increase the versatility of the population data; users can manipulate, aggregate, or otherwise extensively process census data.

Another source of population data that can be very useful, particulary in the study of specific geographic areas, is census maps. Census outline maps allow the investigator to determine the geographic distribution of populations in specific areas of interest. Maps that are available for use with 1980 census data vary according to the resolution needed (refer to Figure 5) and conform to the geographic units already described in Table 2. The census outline maps available for use with 1980 census data are summarized in Table 7.

Table 4. Relationship of 1980 Summary Tape Files, Printed Reports, and Microfiche

Type of data	1980 STFs	1980 Printed reports		Microfiche	
100%	STF 1	PHC80-V	Advanced Reports	PHC80-1	Block Statistics
		PHC80-3	Summary Statistics for Government Units	STF 1-A	
		PC80-1-A	Number of Inhabitants		
100%	STF 2	PC80-1-B	General Population Characteristics	PHC80-2	Census Tracts
		HC80-1A	General Housing Characteristics		
Sample	STF 3	PHC80-3	Summary Characteristics for Government Units

Table 7. Census Outline Maps

Map series	Map scale	Number of map sheets	Size of map sheets	Availability	
				in reports	separate
METROPOLITAN MAP SERIES cover urbanized areas of SMSAs and contain all census boundaries down to the block level	1" = 2,000'	Varies according to size of urbanized areas	18" x 24"	HC(3)	From $1.50 each sheet[1]
COUNTY MAPS-contain boundaries, minor civil divisions, census county divisions, incorporated places, tracts, and enumeration districts	Generally, 1" = 2 miles	Varies from 1 to as many as 64 per county	Generally, 18" x 24"	-	From $1.50 each sheet[1]
PLACE MAPS-for incorporated and unincorporated places; contain tract and enumeration district boundaries	Varies according to size of place; range from 1" = 400' to 1" = 1,500'	Generally, 1 map sheet per place	Varies according to size of place	HC(3)	From $2.25 each sheet[1]
COUNTY SUBDIVISION MAPS-contain information similar to county maps and include township and city boundaries	Generally, 1" = 12 miles	Generally, 1 map sheet per state	3' x 4'	PC(1)-A	$1.00 each sheet[2]
TRACT OUTLINE MAPS-show tract boundaries and incorporated limits for places of 25,000 or more population	Varies according to size of SMSA and complexity of tracted areas; range from 1" = 1/2 mile to 1" = 10 miles	Generally, 2 map sheets per SMSA	Generally, 22" x 24"	PHC(1)	Prices vary[1]
URBANIZED AREA MAPS-shows the extent of urbanized areas by grey shading	Generally 1" = 4 miles	Generally, 1 map sheet per UA	17" x 22"	PC(1)-A HC(1)-A	-
UNITED STATES MAP OF COUNTIES-contains boundaries for counties and equivalents	115,000,000	1 map sheet	30" x 40"	-	$1.00 each sheet[2]

---

[1] Available from: Customer Services Branch, Data Users Services Division, Bureau of the Census, Washington, D.C. 20233

[2] Available from: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402, or any U.S. Department of Commerce Field Office.

The metropolitan, tract outline, and county subdivision maps are the key census maps for correlating 1980 census data to sites in urban or rural areas. These map series are issued separately or with specific census publications. Examples of census outline maps for metropolitan and non-metropolitan areas are presented in Figure 7.

Additionally, the Census Bureau issues several series of statistical maps and graphic summaries that display census data in map form. The map series in this category include the GE-50, GE-70, and GE-80 (Urban Atlas) series. These maps, of varying sizes and scales, utilize color schemes to illustrate population and other social and economic census data.

All printed census matter is available for purchase through the Government Printing Office (GPO); all series issued on microfiche, maps, computer tapes, and technical documentation are available directly from the Customer Services Branch at the Bureau of the Census, Department of Commerce, Washington, D.C. These series can be ordered by calling (202) 763-4100 (Customer Services Branch).

The Bureau of the Census will also prepare, on a cost reimbursable basis, special tabulations of data from the 1980 Census based on customer specifications. Such tabulations can cover any specific geographic or subject matter area as long as the requests do not violate confidentiality restrictions. These types of reports are expensive and may require considerable time to produce. Standard reports, tapes, and microfiche should be used whenever possible.

A complete description of the documents and services available from the Bureau of the Census is not within the scope of this volume. This subsection has attempted to briefly describe the documents and data files that would be of most use towards enumerating populations exposed to chemical substances in the ambient environment. For more detailed descriptions of the documents and data files previously discussed, or for information on other services available from the Bureau of the Census, the investigator should contact:

Data User Services Division
Bureau of the Census
Washington, DC 20233
(202) 763-4100

A detailed list of contacts for census data information is provided in Figure 8.

The population data discussed in this report reflect information collected in 1980, and, therefore, are not up-to-date. Population data for large statistical reporting areas or categories (e.g., regions, divisions, states, urban areas, SMSAs) will not have changed

Figure 8 (continued)

significantly since the data were collected. Population estimates for these areas are published each year in Statistical Abstract of the U.S. (Bureau of the Census 1982b). Population data for detailed geographic areas (e.g., census tracts, enumeration districts, block groups), however, may have changed significantly since the data were collected. The Bureau of the Census does keep records of major population shifts and also has developed procedures and methodologies to estimate populations for periods between the decennial Censuses. A description of the procedures and methodologies is not within the scope of work of this volume. Information on these subjects may, however, be obtained from the Bureau of the Census at the above listed address.

2.3.2 Enumeration of Populations Exposed via Inhalation

As discussed in Subsection 2.2, populations exposed to chemical substances in the ambient environment via the inhalation route are identified on the basis of their geographic location with respect to the atmospheric source of the chemical substances. Atmospheric sources include airborne releases resulting from industrial processes, consumer products, disposal, incineration, transportation activities (e.g., spills and vehicular exhausts), stationary combustion processes (e.g., home heating), and airborne releases of unknown origin.

For the purposes of predicting ambient concentrations of the chemical substance and for purposes of identifying the population exposed, these atmospheric sources are divided into three categories: (1) point sources, (2) area sources, and (3) line sources. The following subsections present methods for enumerating the identified population in each of these three source categories. The methods have been developed keeping in mind the atmospheric modeling tools available to EPA and the major data bases that contain population information (discussed in the preceding section). The methods recommended have also been developed after consideration of the strengths and weaknesses of previous enumeration efforts or on-going efforts in other EPA offices. The following discussions, therefore, also include a review of any historical methods considered relevant to the recommended procedures.

(1) Point Sources. This subsection presents a procedure for enumerating populations exposed to atmospheric concentrations of chemical substances released from point sources. This subsection also presents a procedure to enumerate populations around point sources that are too numerous to deal with individually. These are called prototype point sources or, as frequently cited in the literature, general point sources. Both procedures initially rely on the estimate of atmospheric concentrations via a computer based atmospheric fate model. The acquisition of the population data is, however, operationally different. Enumeration of exposed populations around point sources requires

site-specific population data. Enumeration of populations around prototype point sources uses population density data for different Census defined geographic statistical categories depending on where the sources are located.

The recommended procedure for enumerating exposed populations around point sources is to use an integrated computer based fate model and population data retrieval program known as ATM-SECPOP, developed by the EPA Office of Toxic Substances, Exposure Evaluation Division (OTS-EED), and General Software Corporation. ATM-SECPOP integrates the output of a concentration prediction model, a population distribution data base, and graphic and mapping information displays. The integration affords a rapid and efficient means of generating and presenting exposure-related data resulting from the airborne release of chemical substances from point sources.

ATM-SECPOP estimates concentrations of chemical substances and enumerates the population exposed to these concentrations around point sources that release the chemical to air. The program combines the output of the Atmospheric Transport Model (ATM) (Patterson et al. 1982) and population data contained in the proprietary 1980 Master Area Reference File (MARF) (1980 Census Data) which is accessed via a population distribution model called SECPOP.

ATM calculates pollutant concentrations around a point source by combining data on the facility location, data on emission source characteristics, physiochemical data on the chemical of interest, and stored data on localized meteorological conditions. Pollutant concentrations are estimated for radial sectors around the point source as delineated by axes running in the 16 compass directions and 10 concentric rings at 0.5, 1, 2, 3, 4, 5, 10, 15, 25, and 50 kilometers from the source (illustrated in Figure 9). Concentrations are, therefore, calculated for a total of 160 sectors around the source. The user also has the option to specify the ring distances to which concentrations of the chemical substance will be calculated. Detailed information on the application and data input requirements of ATM are provided in Volume 2 of this series and in the GEMS Users Manual (GSC 1983).

MARF is a data file released by the Bureau of the Census, as previously discussed in Subsection 2.3.1, to which Donnelly Marketing, Incorporated has added the latitude-longitude coordinates of all ED/BGs in the U.S. The 1980 population and housing data in the file, therefore, may be accessed for geographic exposure analysis. The file contains records for states, counties, county subdivisions, places, census tracts, enumeration districts (EDs) in unblocked areas, and block groups in

blocked areas. Each record shows the total population by five race groups, population of Spanish origin, number of housing units, number of households, and number of families.

OTS-EED has recently acquired MARF and entered it into their Graphical Exposure Modeling System (GEMS) (GSC 1983). The file has been integrated with ATM via the SECPOP program. The SECPOP program retrieves the number of people or housing units within each radial sector defined by ATM. The concentration and population data are combined to provide tables on the estimated number of people exposed at various concentration levels. Figure 10 is a sample summary table of the output of an ATM-SECPOP model run.

GEMS also has graphic display capabilities. These functions may be used to illustrate the relationship of variables such as the distribution of exposure or concentration versus distance for any or all directions around a facility. GEMS provides prompts to the user to help in identifying other variables, which may be graphically displayed. Graphic displays may be in the form of bar charts and scatter plots as illustrated in Figures 11, and 12. The relative value of variables may also be displayed in "Rose" diagrams as illustrated in Figure 13. GEMS also has mapping capabilities for use in displaying the geographic distribution of ED/BGs around a facility as illustrated in Figure 14. A complete description of GEMS' capabilities is provided in the GEMS Users Manual (GSC 1983). Because of the proprietary nature of the data contained in MARF, ATM-SECPOP's use is restricted to personnel and contractors of EPA-OTS. Special arrangements for outside parties to use the data are, however, available. Inquiries should be directed to the Chemical Fate Branch Modeling Team of EPA-OTS.

Method 2-2 summarizes the data requirements and steps necessary to enumerate populations via the ATM-SECPOP program. A complete sample computer run of ATM-SECPOP for the point source emission of trichloroethane is provided in Appendix A-1 to this report.

The MARF data retrieved by SECPOP do not include the distribution by age and sex of the populations within the sectors, nor do they contain the additional census data in the 20 percent census count such as occupation, income, travel time, and form of transportation. This information must currently be obtained from forthcoming Census Bureau publications or STF 3 as discussed in Section 2.3.1 of this report. Numerous private sources of population data are also available; marketing companies can provide demographic data for particular geographic areas for a fee.

Point sources may at times be too numerous to deal with individually. This must be determined on a case-by-case basis and may be due to financial and manpower limitations or because the specific

Figure 14. Sample of ATM-SECPOP Mapping of ED/BGs Around a Point Source

Method 2-2. Enumeration of Populations Exposed via Inhalation to Atmospheric Concentrations of Chemical Substances Released from Point Sources

Step 1 Identify the location of the point source(s). Locations can be identified by latitude-longitude or by ZIP code. Latitude-longitude of point source(s) is preferred for reasons of accuracy.

Step 2 The investigator has the option to obtain: (1) concentration and exposed population data via ATM-SECPOP or (2) only population data within radii and sectors around a point source via SECPOP. For population data only, proceed to Step 3. To estimate the atmospheric concentration of the chemical substance around the point source(s) via ATM, it will be necessary to gather site-specific or generic emission characteristics of the point source(s) and chemical substance of interest. It will also be necessary to gather information on the physiochemical properties of the chemical substance. Volume 2 of this series discusses sources of information on site-specific and generic emission characteristics, and physiochemical properties of chemical substances required for ATM.

Step 3 Run ATM-SECPOP. The user must log on the GEMS system at 484-4540 or 4541 with an appropriate account number and password. GEMS is a "user friendly" system and will prompt the user according to the required data entries and available default values. Information on GEMS or ATM-SECPOP may be obtained from the GEMS User's Manual (GSC 1983) or from the EPA-Chemical Fate Branch Modeling Team, Exposure Evaluation Division, Office of Toxic Substances. Concentration results can be plotted graphically against population data. The investigator should consult graphic capabilities of GEMS.

Option

To access population data only, the user, on the first operational prompt, should enter GEODATA HANDLING (GH) operation, then either the Census Data (CD) or Radii-5 (R) procedure to generate a data table or map display, respectively. Follow prompts for entering latitude-longitude (or ZIP code) and the band or distance from the source for which population data are desired. The data resulting from the Census Data procedure will be population count and number of housing units in tabular form. If the user requires the data to be plotted on a map (see Figure 14) and aggregated by distance and direction, he should enter RADII 5 in place of code CD

Note: The EPA-OTS Chemical Fate Branch Modeling Team can also extract population records by state and region from MARF for specific exposure assessment efforts. Population data can then be retrieved by the user according to counties (using FIPS code) and SMSAs. The modeling team requires advance notice for this type of operation because it is more complex then the two previously described procedures.

locations of the point sources are unknown. Preliminary exposure assessments may also require only order-of-magnitude estimates of concentrations and exposed populations. In each of these cases, the estimation of atmospheric concentrations of a substance can be based on the development of a prototype point source. Generic emission characteristics representative of the point sources of interest are gathered, and concentrations are modeled via ATM for one or a series of locations to represent the range of possible ambient air concentrations around the sources. Volume 2 of this series provides a detailed discussion on the development of prototype point sources.

The enumeration of exposed populations also depends on the development of a prototype. The population prototype in turn depends on area and the estimated population density for each of the ATM-defined radial sectors (see Figure 9). The product obtained by multiplying these two pieces of data is an average population for the radial sector of interest. The populations within sectors are then aggregated for radial sectors of equal atmospheric concentration.

Several levels of effort are possible in enumerating populations around prototype point sources. The level of effort is determined by the available locational information for the point sources of interest. The population prototype can be developed with the following population density data:

1. Specific SMSA population densities.
2. Regional population densities.
3. National population density.
4. Regional or national population densities for Census defined geographic statistical categories (i.e., urban, metropolitan, and rural).

If the point sources of interest can be located according to SMSAs, the specific SMSA population density should be used to create the prototype. SMSA population densities can be obtained from the U.S. summary for Number of Inhabitants (Bureau of the Census 1983a) or General Population Characteristics (Bureau of the Census 1983b). Statistical Abstract of the U.S. (Bureau of the Census 1982b) also provides the land area and yearly updates of the population for each of the SMSAs in the U.S., from which up-to-date SMSA population densities can be calculated.

If the point sources of interest can be located only according to regions or if locational data are completely lacking, regional or national population densities can be used to calculate the average population in each of the ATM radial sectors. Population densities for regions and the U.S. are listed in Table 8.

If the location of the point sources can be determined according to the Census defined geographic statistical categories (e.g., urbanized, metropolitan (SMSAs), or nonmetropolitan), the population densities for each of these categories should be used to create a population prototype. To illustrate this approach, prototypes for sources located in urbanized, metropolitan, and nonmetropolitan areas have been created. This was accomplished as previously mentioned by calculating the land area of each radial sector defined by ATM and then multiplying the area by the respective population density of the geographic category. Population densities of 1,033 persons/km^2 for urbanized*, 120 persons/km^2 for metropolitan (SMSAs), and 8 persons/km^2 for non-metropolitan areas were used (Bureau of the Census 1981b). Results of these calculations are presented in Table 9. It is important to note that when the population prototypes for urbanized and metropolitan areas were calculated, the respective densities were only applied to the radial sectors within radial rings that correspond to the average radius of urbanized and metropolitan areas. The average radii of 8 km and 26 km for urbanized and metropolitan areas in the U.S., respectively, were calculated by dividing the total U.S. land area for each category by the number of areas in the U.S. of each (Bureau of the Census 1981b). This average area was assumed to equal the area of a circle in order to back-calculate the radius.

The enumeration of populations exposed to chemical substances released from prototype point sources known to be located in one of these statistical categories is now possible by using the results presented in Table 9. The population estimates for each radial sector should be linked to the ATM-calculated concentration estimates for each sector (or radial ring) of the prototype point source. Populations should then be summed for all sectors of equal concentration to estimate the total exposed population for each concentration. These results are then multiplied by the number of sources to calculate the total population exposure distribution in the U.S. Method 2-3 summarizes the basic procedural steps for enumerating populations around prototype point sources.

This procedure is an approach to enumerating populations exposed via inhalation to atmospheric concentrations of chemical substances released from point sources too numerous to deal with individually. Each exposure assessment for a chemical substance should have an approach tailored to the available information for the point sources and chemical substance of

Method 2-3 Enumeration of Populations Exposed via Inhalation to Chemical Substances Released from Prototype Point Sources

Step 1 The materials balance or information on the production and use of a chemical substance will identify the number of point sources to be considered. The location of these sources should be further identified according to cities, SMSAs, regions, counties, or a Census defined geographic statistical category (e.g., urbanized, metropolitan, or non-metropolitan). Volume 2 of this series provides information on data bases, documents, and associations that may aid in locating point sources.

Step 2 Using generic emission characteristics and site-specific meteorological data stored in GEMS that is representative of conditions around a typical facility, perform an ATM run (see Method 2-2). Volume 2 of this series also provides detailed information on the development of prototype point sources. The GEMS Users Manual (GSC 1983) describes meterological data stored to support ATM simulations.

Step 3 Using population densities for the locations of the point sources (e.g., SMSAs, regions) or the data in Table 9, calculate or record the average population for each radial sector or within each radial ring (radial sector population X16). The population in each radial sector or ring should then be matched to the concentration or range of concentrations predicted for each radial sector or ring around the prototype point source. Populations should then be aggregated for all radial sectors or rings of equal concentration.

Step 4 Multiply the Step 3 results by the total number of point sources in the U.S. to enumerate the total exposed population at each concentration or possible range of concentrations.

interest. The approach should also be developed according to the level of detail required and should obviously be within the time, financial, and manpower constraints of the effort.

(2) Area Sources. Area sources are sources of atmospheric release of chemical substances so numerous that patterns of concentration can be efficiently analyzed only as a group. Area sources may be either stationary, such as home heating systems, or mobile, such as vehicles. The usual approach to modeling area source emissions is to assume that the emissions are uniformly distributed within a geographic area. Emission rates per unit area (or per capita, household, or vehicle) are estimated, and resulting concentrations for the geographic area are calculated using an appropriate area source model or algorithm. Volume 2 of this series provides details on procedures and models for the calculation of atmospheric concentrations resulting from area source emissions.

Enumerating the exposed population for area sources involves the acquisition of census data for the geographic area of interest. The most straightforward procedure, therefore, is to define the area according to census geography. Census geographic categories include urban areas, urbanized areas, Standard Metropolitan Statistical Areas (SMSAs), central cities, and rural areas; these categories were defined in Table 2. Table 10 summarizes the 1980 population count data for the major census geographic categories and for each of the four census regions in the U.S. Detailed population data for census divisions or for states are available in the summary documents for Number of Inhabitants and Population Characteristics of the U.S. These documents provide precise enumerations of populations based on decennial Censuses. Statistical Abstracts of the U.S., published yearly, also supplies population count data for many of the census categories. The population data in this document are based on the most recent Census and are updated yearly by Census Bureau projections.

The major problem with the use of census data to estimate populations around area sources is that no information is available on the differential levels of exposure to the populations residing in the geographic areas. Systems Applications, Inc. (SAI 1980) has presented a method of estimating differential exposures within geographic areas by distributing national area source emissions among different size cities (as determined by population) according to number of motor vehicles, heating day requirements, and population density. For detailed information, the investigator should consult the SAI document (SAI 1980). Unless finances and manpower are plentiful, the approach discussed in the preceding paragraph is an efficient procedure for enumerating populations exposed via inhalation to chemical substances released from area sources. Method 2-4 summarizes the required procedural steps.

Table 10. 1980 Population Data for the U.S. and Regions by Census Geography

		Region			
	U.S.	Northeast	North Central	South	West
Total Population	226,504,825	49,136,667	58,853,804	75,349,155	43,165,199

Method 2-4. Enumeration of Populations Exposed via Inhalation to Atmospheric Concentrations of Chemical Substances Released from Area Sources

Step 1 Determine the demographic category and geographic location of the area source from the production, use, and environmental release data for the chemical substance. Demographic categories for which census data are available include:

- Urban Areas
  - urbanized areas
  - other urban areas
- Standard Metropolitan Statistical Areas
  - central cities
  - outside central cities
- Nonmetropolitan Areas
- Rural Areas

The nature of the source determines which category should be used to define the area. Urban areas or central cities may be of concern with respect to vehicular exhaust or dry cleaning solvents; rural locations may be area sources of pesticides used in farms and gardens.

Step 2 Enumerate the population for demographic and geographic category of interest from Table 10. If more detailed data are required (e.g., census division, state), retrieval of population data in MARF according to specific areas is possible using the GEODATA HANDLING (GH) operation and Census Data (CD) program of GEMS as previously described in subsection (1) and Method 2-2. Population data are also available in the the U.S. summary of Number of Inhabitants or General Population Characteristics. Statistical Abstract of the U.S. will also provide population data for many of the demographic categories listed, based on updates from the 1980 census year.

(3) Line Sources. This section presents a method for enumerating populations exposed to chemical substances released from line sources. As defined in Section 2.2, line sources are predominantly sources of airborne release of chemical substances along transportation corridors, such as highway and railroad lines. Other types of releases from line sources also exist, such as the volatilization of chemical substances from waterways and fugitive emissions or spills and leaks that occur along pipelines used to transport chemical substances. These types of releases are not specifically addressed in this section; however, the general principle of the methodology presented is applicable to them.

The only existing method identified for enumerating populations exposed to chemical substances released from a line source was developed for the U.S. Department of Commerce, Maritime Administration (ADL 1974). The method was developed to calculate the safety hazards resulting from different modes of transportation of hazardous substances. Basically, the method requires data on the length of the line source (or transportation corridor), the width of the area adjoining the line source affected by the release of the chemical substance, and the population densities along the line source. The total area affected by the chemical substance is calculated by multiplying the length and width of the affected area. Total area affected is then multiplied by population densities to enumerate the exposed population.

The method developed for the Maritime Administration assumes that all line sources of chemical release are straight lines that pass through metropolitan areas, nonmetropolitan areas, or combinations of both. Metropolitan areas are defined as those designated Standard Metropolitan Statistical Areas (SMSA) by the Census Bureau. Nonmetropolitan areas are defined as all areas outside SMSAs.

For a line source that begins and terminates in an SMSA, the following procedure for calculating the length of the line which passes through metropolitan and nonmetropolitan areas was developed:

The SMSA for each principal city along the origin-destination route is recorded in units of square miles according to census data. This area is then converted to a circular configuration with the principal city located at its center. If the line source (the vehicle or transportation corridor) travels completely through an SMSA, then the hypothetical diameter of each SMSA is assumed to be equivalent to the length of the metropolitan population corridor exposed to the chemical substance of interest. If the line source originates or terminates in an SMSA, then the length of the metropolitan population corridor is assumed to be equal to the hypothetical radius of the SMSA. The length of the nonmetropolitan population corridor, therefore, is equal to the total distance between the beginning and end of the line source minus the calculated length of the metropolitan population corridor. This procedure for calculating metropolitan and nonmetropolitan population corridor lengths is illustrated in Figure 15.

NOTE: SEE APPENDIX A-1, PROBLEM 5 FOR DEMONSTRATION OF METHOD

Figure 15. Schematic Representation of the Procedure to Enumerate Populations Exposed to Chemical Substances Released From a Line Source

The width of the line source is defined according to an appropriate algorithm or model using emissions characteristics of the pollutant and meteorological conditions (wind speed, direction, and atmospheric stability). The total metropolitan area exposed is calculated as the product of the length and width of the metropolitan corridor. The same procedure is followed for calculating the total nonmetropolitan area exposed. The calculated areas are then multiplied by the average metropolitan (SMSA) and nonmetropolitan (non-SMSA) population density, respectively, to enumerate the total exposed population.

This procedure for enumerating populations exposed to chemical substances released from a line source is believed to be a suitable approach for the current needs of OTS-EED. One of the main data requirements of the ADL approach is the length of the line source. These data are generally provided on a chemical-specific basis in the exposure assessment process.

Detailed information on methods to calculate the length of line sources related to transportation spills is available in Volume 9 of this series. Statistical Abstract of the U.S. (Bureau of the Census 1982b) is also an excellent source on such generic data as metropolitan and non-metropolitan highway mileage, inter-city bus lines, and railroad mileage for the total U.S. and the individual states. For detailed geographic resolution, the topographic maps published by the U.S. Geological Survey are the recommended tool for obtaining the length of a particular line source. Since most of these maps also include plots of metropolitan and nonmetropolitan areas, it is also possible to rapidly determine the length of the line in each category.

Calculation of the width of the line source corridor requires the use of one of several line source simulation models. Line source simulation models consider emission characteristics and meteorological conditions to determine concentrations at various distances downwind of the source. Currently, OTS-EED does not have any line source models integrated into GEMS. The UNIVAC version of HIWAY is included in the EPA-OTS computer file library and, therefore, is available to the OTS-Modeling Team. Additional information on line source models is provided in Volume 2 of this series.

The final data requirement for enumerating the exposed population is the population density for the area of interest. Population densities for all SMSAs are available in the Census summary document Number of Inhabitants (PC-80-1-A). Population densities for cities with 100,000 or more inhabitants are available in Statistical Abstracts of the U.S. (Bureau of Census 1982b). Population densities for specific urban areas with populations less than 100,000 (but greater than 2,500) are available in the Census summary document General Population Characteristics (PC-80-1-B).

Finally, Table 8, previously presented, lists population densities for the different Census Bureau classifications based on 1980 Census data. The population densities obtained from the above listed documents or from Table 8 are then multiplied by the area of the line source corridor to enumerate the total population.

Method 2-5 summarizes the procedure for enumerating populations exposed via inhalation to chemical substances released from line sources. A demonstration of the method on a theoretical line source problem is presented in Appendix A-1 (Problem 5).

2.3.3 Enumeration of Populations Exposed via Dermal Contact

Dermal exposure to chemical substances in the ambient environment may occur through a number of pathways. One activity has been identified as having the greatest potential for significant exposure: swimming in contaminated surface waters. Methods for estimating the size of the population involved in that activity are presented in Method 2-6.

Approximately 101.7 million persons swim in U.S. surface waters (Bureau of the Census 1982b); this represents 45 percent of the U.S. population. The technique for estimating the number of swimmers contacting water contaminated by a particular substance depends on whether the exposure source was identified through monitoring data or through examination of the chemical's release information. Volume 2 of this series discusses identification of sources of chemicals released to surface water.

Geographically defined areas of aquatic exposure, such as river reaches downstream of an industrial discharge, may be identified by examining release information. The exposed population is therefore the swimmers in those specified receiving waters. The most reliable method for estimating the number of persons exposed to contaminants in surface waters is to contact regional authorities, such as the state, city, or county department of parks. These authorities can identify affected recreational areas and estimate the extent to which they are used.

Another approach to enumerating that population is to obtain a figure for the total population for the region using the water body as a source of recreation, then to multiply that total by 45 percent, the fraction of persons who swim. There are limitations to this estimation technique; determining the region that uses a recreational facility, such as a lake or river, is difficult. Matching that region to a census-defined geography for which population data are available may also present problems. If necessary, the area may be broken into block groups or

Method 2-5. Enumeration of Populations Exposed via Inhalation to Chemical Substances Released from Line Sources

Step 1 Calculate the length of the line source as illustrated in Figure 15. Sources of information on the calculation of the length of the line source include Volume 9 of this series Methods for Estimating Exposure to Chemical Substances Resulting from Transportation Related Hazardous Materials Spills and A Modal Economic and Safety Analysis of the Transportation of Hazardous Substances in Bulk (ADL 1974). Generic data for line source lengths can be obtained from Statistical Abstracts of the U.S. (Bureau of the Census 1982b) or from government agencies and associations such as U.S. Department of Transportation - Federal Highway Administration and Federal Railroad Administration; the U.S. Interstate Commerce Commission; Bureau of the Census - Transportation Surveys; Association of American Railroads, Washington, D.C.; American Bus Association, Washington, D.C.; and American Public Transit Association, Washington, D.C.

Step 2 Calculate the area affected by the released pollutant. This may be accomplished by calculating the width of the exposed corridor using an appropriate line source model. Data on the emissions characteristics and meteorological conditions are required for most of the available line source models. Exposed area is the product of the length of the line source and the corridor width.

Step 3 Enumerate population by multiplying the population density of the exposed area by the calculated area exposed (Step 2). Population densities for specific census divisions, states, and urban areas based on the 1980 Census are available in the Census Report General Population Characteristics: U.S. Summary. Population densities for SMSAs are available in the Census document Number of Inhabitants: U.S. Summary. Table 8 lists generic population density data that would also be valuable where detailed or specific data are not required. If more resolution is required for urban areas, population estimates can be refined by consulting maps of ED/BGs to determine which ones fall into the affected area. Populations can be summed for these ED/BGs to provide a more accurate estimate than that given by the product of area and average density.

Method 2-6. Enumeration of Populations Exposed via Dermal Contact

Determine the number of swimmers contacting contaminated ambient surface waters.

Option 1 - (contamination identified by monitoring data or release information) contact the local authorities to identify impacted recreational areas. Inquire about the area's use to estimate the number of affected persons.

Option 2 - (contamination identified by monitoring data). Multiply the frequency of detection in percent by the total population of swimmers, 101.7 million persons. (This option yields a very crude estimate of the exposed population. It assumes that the monitoring data are from a nationwide survey of all potential swimming locations or that they are from a sampling that is statistically representative of all swimming locations.)

Option 3 - (contamination identified by release information). Identify the water bodies of concern. Enumerate the total population within a 50 mile radius or corridor, using data in General Population Characteristics for census-defined geographies such as cities, towns, counties, or SMSAs. Multiply the total population of the area by 45 percent, the fraction of persons who swim in surface waters.

Option 4 - (contamination identified by monitoring data). If extensive nationwide monitoring data are available, they can be used to identify the affected water bodies. The procedure to enumerate the number of swimmers exposed to the chemical substance is the same as in Option 3.

enumeration districts, then reaggregated. It is reasonable to assume that a body of water within 50 miles of a person (a one-hour drive) may be used as a source of recreation. The investigator might assume that the population within that radius or corridor is potentially exposed. The General Population Characteristics for the area should be consulted, and the total population of counties, towns, SMSAs, etc., within the radius or corridor should be totaled.

For contaminants introduced by sources other than point discharges of effluents, geographic definition of potential exposure may not be possible. Monitoring data retrievals from STORET or similar data bases can then be used to indicate the prevalence of waterborne pollution for a chemical substance. If enough data are available, an estimate of the number of persons dermally exposed via swimming can be obtained by multiplying the frequency of detection of the contaminant in surface water (in percent) by the participating population (101.7 million persons).

These population enumeration techniques assume that persons will swim in contaminated waters as often as in noncontaminated lakes and rivers. Figures obtained by these methods may therefore be overestimates. That assumption is not, however, unreasonable; low level contamination that may cause human exposure is not always detectable.

2.3.4 Enumeration of Nonhuman Populations

Nonhuman populations are generally more difficult to quantify than are human populations because less information is available, and the data that are available are often measured in units other than numbers of organisms; populations may, for example, be expressed as herds or biomass. The adequacy and sources of nonhuman population data vary considerably, depending on the organism. As might be expected, most research effort has been invested in plant and animal species that have economic significance.

In most cases, it is necessary to gather the data from diverse sources to enumerate nonhuman populations. The major sources available include journal articles and other publications, federal and state agencies, and selected private agencies. A literature search, using computerized data bases such as the following, is recommended:

> AGRICOLA (National Agricultural Library, Beltsville, MD)
> AGRICOLA is the cataloging and indexing data base of the National Agriculture Library. It provides comprehensive coverage of worldwide journal and monographic literature on agriculture and related subjects.

ASFA (NOAA/Cambridge Scientific Abstracts, Bethesda, MD)
The Aquatic Sciences and Fisheries Abstracts (ASFA) is a comprehensive data base on life sciences of the seas and inland waters as well as related legal, political, and social topics. It includes information on aquatic biology, oceanography, fisheries, and water pollution.

BIOSIS PREVIEWS (Biosciences Information Service, Philadelphia, PA)
BIOSIS PREVIEWS provides comprehensive worldwide coverage of research in the life sciences. It contains citations from Biological Abstracts and Biological Abstracts/RRM.

Life Sciences Collection (Cambridge Scientific Abstracts, Bethesda, MD)
Life Sciences Collection contains abstracts of worldwide journal articles, books, conference proceedings, and report literature. The information includes animal behavior, ecology, and entomology.

SSIE Current Research (Smithsonian Science Information Exchange, Washington, D.C.)
SSIE Current Research contains reports of both government and privately funded scientific research projects either currently in progress or initiated and completed during the most recent two years.

These and other data bases can be accessed through DIALOG Information Retrieval Service (DIS 1982).

In addition to these data bases, a retrieval from the Fish and Wildlife Reference Service and a retrieval from the GEOECOLOGY Data Base may be worthwhile. The reference service is operated by the U.S. Fish and Wildlife Service out of Denver, Colorado. Computerized literature searches, covering the published and unpublished fish and wildlife research reports resulting from federally funded programs, are conducted for a fee of $30. The GEOECOLOGY Data Base (Olson et al. 1980), maintained by the Oak Ridge National Laboratory, Oak Ridge, Tennessee, is a compilation of computerized environmental data. The data base includes, at the county level of resolution, selected data on terrain and soils, water resources, forestry, vegetation, agriculture, land use, wildlife, and endangered species. The wildlife sector includes information from the annual Breeding Bird Survey, data on federally designated endangered and threatened species, and the geographic range of various mammals. The Endangered Species File and Code Dictionary of the GEOECOLOGY data base is currently available through the EPA-OTS computer library (Files W09 and W10, respectively). Requests for information or retrievals for the other data included in GEOECOLOGY should be directed to:

Dick Olsen
GEOECOLOGY Project Team
Oak Ridge National Laboratory
PO Box X, Building 1505
Oak Ridge, TN 37830
(615) 574-7819

Estimates of exposed nonhuman population sizes may also be made, if the resources permit, through contact with appropriate state and federal agencies. The two that are of most use are the Fish and Wildlife Service and the U.S. Department of Agriculture's Forest Service. Both maintain regional research offices which may provide published or unpublished population data not available from other sources. Private agencies such as those listed in Table 11 may also be contacted for population information. The National Wildlife Federation (1980) lists many private organizations with specific wildlife concern which may also be used as information sources.

The investigator should be aware that, for most species, the population data, if any, are scant and are based on a handful of studies in specific locales. Extrapolating such data to large regions or to the nation involves considerable uncertainty because uneven spatial distribution and temporal fluctuations are characteristic of many nonhuman populations. Population density is highly dependent on habitat type, and the population density estimated in one local study may be significantly higher or lower than the average population density for larger areas (e.g., counties, states, regions).

2.4 Characterization of Exposed Populations

The average physiological parameters that determine exposure (e.g., breathing rate, body weight, and skin surface area) are age- and sex-specific. Subpopulations defined by age or sex, such as the elderly or women of child-bearing age, may be especially susceptible to a chemical substance. Characterization of exposed populations permits the determination of exposure distributions and the enumeration of specific high risk subpopulations. Methods for characterizing populations exposed via inhalation and dermal exposure in the ambient environment are presented in the following subsections.

2.4.1 Populations Exposed via Inhalation

The level of geographic resolution necessary to an assessment of atmospheric pollutants dictates the scheme by which characterization proceeds. Populations near point sources for which ATM-SECPOP is used to determine exposure may be characterized by the use of census data

specific to the area. For prototype point sources, area sources, and line sources, both site-specific and generic data on the age and sex characteristics of the population may be applicable sources of information.

(1) Point Sources Enumerated by SECPOP. The SECPOP data base enumerates the populations differentially exposed in segments around point sources. Data for geographically-defined areas within the SECPOP radius are available from the Bureau of the Census.

Populations enumerated by SECPOP can usually be characterized by consulting the General Population Characteristics series for the area within the model radius. The level of detail achievable through this data source will be sufficient for all but the most in-depth exposure analyses; Table 2 (Section 2.3.1) lists the census-defined areas for which age and sex data are available from General Population Characteristics.

Segments within the model radius can also be segregated into census tracts if more detail is required. Series PHC80-2, Census Tracts, presents data by age and sex for populations defined by census tract.

(2) Point, Area, and Line Sources. The data sources discussed above (General Population Characteristics and Census Tracts) can be used to characterize populations around or within these pollutant sources. Point, area, and line sources are, however, often too numerous to be treated individually. Table 12 presents the age and sex distribution of the U.S. population as determined by the 1980 Census. These data may be used to estimate the distribution of males and females of different ages in relatively large exposed populations; that distribution would be expected to be similar to the national distribution. Method 2-7 is a guide to characterizing exposed populations.

2.4.2 Populations Exposed via Dermal Contact

Numerous activities in the ambient environment may lead to dermal contact with chemical substances: aquatic recreation, gardening and other contact with the soil, and contact with atmospheric pollutants deposited on the skin surface. Of these, one is considered to be a potentially significant source of exposure: swimming in contaminated surface waters.

As discussed in Section 2.3.4, a large proportion of the population swims in lakes, rivers, and the ocean. It can be assumed that such a large population constitutes a cross section of the U.S. populace and that swimmers can be characterized by the data in Table 12. It is likely that the actual swimming population is skewed somewhat toward the young, and that the young swim more frequently, but data to substantiate that premise are not available.

Table 12. Population of the United States
by Age and Sex: April 1, 1980

Age and sex	Population	Percent
1. Both sexes		
All ages	226,504,825	100.00
Under 5	16,344,407	7.22
5-9	16,697,134	7.37
10-14	18,240,919	8.05
15-19	21,161,667	9.34
20-24	21,312,557	9.41
25-34	37,075,629	16.37
35-44	25,631,247	11.32
45-54	22,797,367	10.65
55-64	21,699,765	9.58
65-74	15,577,586	6.88
75-84	7,726,826	3.41
Over 85	2,239,721	.99
Median age	30.0	
2. Male		
All ages	110,032,295	100.00
Under 5	8,360,135	7.59
5-9	8,537,903	7.76
10-14	9,315,055	8.46
15-19	10,751,544	9.77
20-24	10,660,063	9.69
25-34	18,378,764	16.70
35-44	12,567,786	11.42
45-54	11,007,985	10.00
55-64	10,150,459	9.22
65-74	6,755,199	6.14
75-84	2,865,974	2.60
85 +	681,428	0.62
Median age	28.8	
3. Females		
All ages	116,472,530	100.00
Under 5	7,984,272	6.85
5-9	8,159,231	7.00
10-14	8,925,864	7.66
15-19	10,410,123	8.94
20-24	10,652,494	9.15
25-34	18,696,865	16.05
35-44	13,063,461	11.22
45-54	11,789,382	10.12
55-64	11,549,306	9.92
65-74	8,822,387	7.57
75-84	4,860,852	4.17
85 +	1,558,293	1.34
Median age	31.3

Method 2-7. Characterization of Populations Exposed to Chemical Substances via Inhalation of Ambient Air

For populations near point sources (as enumerated by SECPOP), line sources, or area sources, choose the option providing the desired level of detail. The method of enumeration and the financial and manpower resources allotted will dictate the choice of options.

Option 1 - The most detailed characterization is obtained by determining census tracts within the defined radius, area, or corridor and using the age-sex distributions for each (in Census Tracts) to describe the population.

Option 2 - General Population Characteristics for the area (SMSA, county, town, etc.) provides the age and sex characterization for the enumerated population.

Option 3 - The generic data in Table 12, describing the U.S. population as a whole, may be used to characterize populations around point, general point, area, or line sources.

3. POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES IN THE OCCUPATIONAL ENVIRONMENT

3.1 Introduction

This section presents methods for enumerating and characterizing occupationally exposed populations. The methods described apply to workers in industry, trade, and commercial establishments. The data provide various levels of detail that enable the user to produce both preliminary and in-depth assessments.

Figure 16 is a flow diagram of the three-stage method framework. Included in the diagram are some of the major data sources used.

The identification of the exposed population is discussed only briefly in this section (Subsection 3.2); the occupational exposure assessment methods report (Volume 6) describe the process in detail.

The enumeration of the exposed population relies on the direct utilization and combination of numerous data bases. This information is largely the result of efforts by the federal government to monitor employment; as such, the data may not be in a format directly applicable to exposure assessments. Subsection 3.3 addresses the limitations of the data and how they can be used for occupational population studies.

The age and sex of a worker affect physiological parameters that determine exposure (e.g., breathing rate, skin surface area). Detailed exposure assessments may require that populations be described by age and sex distributions; Subsection 3.4 discusses methods of characterizing workers by age and sex.

Examples of the use of the methods in this section of the report are presented in Appendix A-2.

3.2 Identification of Exposed Populations

Methods for identifying occupationally-exposed populations are summarized herein; Volume 6 of this series provides details on these methods. Specific job titles and 4-digit Standard Industrial Classification (SIC) designations are the most common forms by which employment is listed. Identification should be keyed to this fact when possible. Method 3-1 summarizes the general approach to population identification.

Figure 16. Three-stage Framework for Enumeration and Characterization of Occupationally Exposed Populations

Method 3-1. General Procedure for Identifying Populations Exposed in the Workplace

Step 1 Determine which industries and types of establishments produce, process, use, and sell the chemical substance of concern. Locate major production and use facilities. Identify the applicable SIC codes for all industries and establishments (see Volume 6 of this series).

Step 2 Consult the production, use, and release information and available monitoring data to identify points of chemical release and possible exposure pathways and exposure routes. Identify activities leading to exposure (see Volume 6).

Step 3 For each industry and activity identified in Steps 1 and 2, list the workers potentially exposed by occupation or job title. Use the Industry-Occupation (I-O) matrix as a guide in listing.

Employees potentially exposed via inhalation, ingestion, and dermal contact may be identified by examining workplace monitoring data or by considering the workers' process equipment and job activities.

Monitoring data are usually available only for a relatively small number of existing chemicals. New chemicals must be investigated by studying the premanufacturing notice (PMN) submittal and supplementing that information with knowledge of the process. Analysis of monitoring data and production, use, and release information may identify:

- Workers exposed in a particular industry, identifiable by SIC code.
- Persons employed in a specific occupation in an industry.
- Workers exposed by their presence at an industrial site.
- Persons performing certain activities or processes not directly classifiable by occupation (e.g., cleaning, sampling, waste disposal).

These groups are enumerated by methods specific to each. The following section discusses the methods by which exposed populations can be enumerated. Most of the methods rely upon direct use of data bases maintained to monitor employment levels. As mentioned previously, the data may not match the identified populations; adaptation of the information is discussed.

3.3 Methods for the Enumeration of Exposed Populations

This section presents the recommended procedures and data sources for the enumeration of occupationally-exposed populations. The methods may often be used in combination with each other to achieve the best estimate of workers exposed to chemical substances, though common sense must be used to avoid double-counting subpopulations. The method or methods to be used are often dictated by the identification scheme.

This section is divided into three subsections, based on the categories for identifying the exposed populations. Subsection 3.3.1 discusses data bases and methods based on the Standard Industrial Classification (SIC) codes. Populations identified by occupation and industry are discussed in Subsection 3.3.2, and Subsection 3.3.3 deals with site-specific worker populations.

Some of the methods discussed in this section provide better estimates than others. The greater the level of detail available, the better the estimate of the exposed population; thus, the methods based on specific occupation by industry or activity data are generally better than the SIC-based method. The limitations of each type of data are discussed in each section. Examples of the data available for many of the methods are included as Appendix B to this report. Appendix A-2 presents examples of applying the methods in this section.

3.3.1 Enumeration of Populations Identified by SIC Code

The method for enumerating workers identified by SIC code (Method 3-2) is straightforward and relies on the use of two types of information: (1) the Bureau of Labor Statistics' Employment and Earnings (U.S. Department of Labor 1981a) and (2) the Economic Census and related reports.

All SIC-based data have one major limitation. An establishment may be involved in activities classifiable under numerous 4-digit SIC codes, but all data are reported under one SIC designation (the "major activity" in which the company is involved). This provision simplifies a company's reporting requirements but produces data that may be gross underestimates or gross overestimates when used for exposure assessments. There is no way to account for such discrepancies in occupational population studies.

Another limitation has varying effects on the reported data. Some industries count only paid employees; establishments staffed by unpaid family members or owner-proprietors will therefore be uncounted or undercounted.

A problem with all SIC-based data is the lack of completeness. The list of 4-digit SIC codes runs nearly 80 pages of print, but data are reported for only a fraction of the established 4-digit codes. Some publications are limited by choice, i.e., only specific codes are reported. More often the limitation is related to the need to preserve confidentiality of responses when few data are reported for an industry.

(1) Employment and Earnings. The U.S. Department of Labor's Bureau of Labor Statistics (BLS) publishes Employment and Earnings monthly. The data therein are thus the most recent available; the employment figures in each publication are for the previous month.

The major limitation in the monthly BLS data is the lack of completeness. Only a fraction of the 4-digit SIC codes in manufacturing industries is represented, and nonmanufacturing industries (such as trade, construction, and services) are present at the 3-digit level of resolution at best. Use of data based on the 2- or 3-digit level may result in overestimation of occupational populations, because the broad categories may include industries in which no exposure occurs.

Method 3-2. Enumeration of Populations Identified by SIC Code

Step 1 Determine which source(s) list populations for the SIC codes for which data must be obtained. For nationwide chemical assessments, consult (in order of preference):

- Employment and Earnings (most recent data)
- The Economic Censuses (fairly complete and readily available)
- Other information such as County Business Patterns and the Annual Survey of Manufactures
- When enumerating populations in specific geographic areas, consult County Business Patterns (published last in 1981) or the Geographic Series of the Economic Censuses (accessible in hard copy or through GEMS).

Step 2 Choose the data most representative of the workers actually exposed. In manufacturing industries, for example, "production workers" is generally a better category for estimating exposures during the process than is total employment for a SIC listing (which includes office workers who may not be exposed).

Step 3 Qualify all data by addressing questions of limitations:

- Does the SIC code represent the exposed population? If not, are data overestimates or underestimates?
- Are data based only on paid employees and therefore possibly underestimates?

The BLS establishment data are number of jobs, not number of workers. If a person holds two jobs, he may be reported twice in Employment and Earnings. This, however, is rarely a limitation to the data as they are used in exposure assessments; only workers with both jobs classified under the same SIC code would be double counted in the exposed population for an occupation.

(2) Economic Censuses. Eight Economic Censuses are conducted in five-year cycles:

1. Census of Service Industries
2. Census of Wholesale Trade
3. Census of Retail Trade
4. Census of Manufactures   Years ending in 2 and 7
5. Census of Mineral Industries
6. Census of Construction Industries
7. Census of Transportation
8. Census of Agriculture   - Years ending in 8 and 3

All of the censuses contain information on employment, listed by SIC code. More information on the censuses is available from the Research Triangle Insitute (RTI 1982) and U.S. Department of Commerce (USDC 1979); detailed information on the compilation techniques is presented in the Census publications associated with each Economic Census. The data available in the first six economic censuses are summarized in Table 13. The Census of Transportation's only employment data are listings of truckers "for hire" and "not for hire" (RTI 1982).

Data related to the Economic Censuses include County Business Patterns and the Annual Survey of Manufactures. The County Business Patterns, last compiled in 1977, provide county-by-county and national summary statistics by SIC code for the full range of 2-, 3-, and 4-digit classifications. The reporting requirements and resulting data are similar to those of the Economic Censuses. The Annual Survey of Manufactures is a yearly update of the Census of Manufactures.

Despite their limitations, SIC-based data have proved useful in exposure assessments. This is especially true for widely used chemicals, such as formaldehyde in textile resins. Data from the Census of Manufactures provided useful estimates of textile mill workers exposed to formaldehyde, and the Censuses of Retail Trade and Wholesale Trade were used to enumerate persons exposed as a result of selling formaldehyde-treated cloth and apparel (Versar 1982).

All SIC-based employment data are government-generated and are therefore available to the public. All publications listed in this

Table 13. Data Available in the 1977 Economic Censuses

Census	Number of establishments		Employment			Reports available			Tapes	
	All	With payroll	All	Paid	Production/ construction	Geographic area[a]	Subject series[b]	Industry series[c]	Geographic areas	Industry series
Service industries	x	x		x		53	10	n/a	x	x
Wholesale trade		x		x		52	3	n/a	x	x
Retail trade	x	x		x		52	2	n/a	x	x
Manufactures		x	x*		x	51	17	82	x	x
Mineral industries		x	x*		x	9	8	14	no	no
Construction industries	s	s	s		s	10	n/a	28	no	no

n/a = not applicable.
x = Data available for all census areas down to counties and cities.
s = Data available at the state and national levels only.
* = Separate listings for office and administrative workers available.
[a] Reports data by state and nationally.
[b] Grouped into volumes of related types of businesses for convenient cross-referencing.
[c] Each report deals with one industry.

Source: Adapted from RTI (1982) and USDC (1979).

section can be obtained through the Government Printing Office, and many are available in major D.C. area libraries. The Modeling Team of the Exposure Evaluation Division's Chemical Fate Branch has begun incorporating the Economic Censuses into the Graphical Exposure Modeling System (GEMS). GEMS users can extract data for 3- or 4-digit SIC codes from the Geographic Series of the Censuses of Manufactures, Retail Trade, Wholesale Trade, and Service Industries. Total employment, number of establishments, and (where applicable) production workers can be obtained as national totals or by states, counties, SMSAs, or cities. These data can be statistically analyzed and displayed by GEMS in tabular form or in a variety of graphical presentations (e.g., bar graphs and scatterplots).

3.3.2 Enumeration of Populations Defined by Occupation and Industry

Occupationally exposed populations will often be identified by job title, e.g., by occupation and industry. The most detailed employment information available, the Industry-Occupation (I-O) matrix (U.S. Department of Labor 1981b), is presented in this format. The Bureau of the Census also presents data in that style, though at a much more aggregated level reflecting less detail than the I-O matrix. A third source of this form of occupational data is contact with professional organizations and trade associations. The use of these data is summarized as Method 3-3. Each type of information is discussed below.

(1) The Industry-Occupation (I-O) Matrix. The I-O matrix is a compilation of data collected regularly from the Bureau of Labor Statistics (BLS), state employment agencies, and the Employment and Training Administration of the Department of Labor. The matrix is collated for data in three-year cycles (RTI 1982). The data are actually presented as two matrices encompassing 1,615 occupations in 378 industries. One matrix lists industries by occupation; the printed output of this matrix is about 2,500 pages. The more useful listing of occupations by industry is 5,000 pages long. Both are available on computer tape from BLS; they can be obtained as paper hardcopy and on microfiche from the National Technical Information Service (NTIS). An example of the I-O matrix output is contained in Appendix B-1.

Personnel at the Bureau of Labor Statistics indicate that the publicly-available I-O matrix may be somewhat reduced in scope from its initial conception.* The effect of those changes on the usefulness of the data cannot be projected at this time.

---

*Personal communication with G. Schweer, Versar, and E. Abramson, BLS, Division of Occupational Outlook, May 1982.

Method 3-3. Enumeration of Populations Identified by Occupation and Industry

Option 1	Consult the I-O matrix directory, and enumerate populations listed therein. Employment is read directly off the matrix; no adjustment or extrapolation is necessary.
Option 2	For very specific or unusual occupations, identify the applicable trade or professional organizations. Contact the organization and ask whether data on the number of member's is representative of total employment in that field.
Option 3	In the absence of all other data, estimate the population by consulting Occupation by Industry. If possible, state qualitatively whether the 1970 data provide overestimates or underestimates (more likely).

(2) Bureau of the Census data. The decennial Census collects detailed employment information from one in six respondents for publication as the Occupation by Industry series report (Bureau of the Census 1972). The biggest limitation to the use of the data is that they were last published in 1972, as a result of the 1970 Census. Budget limitations may preclude the publication of Occupation by Industry for the 1980 Census. Data collected in 1980 have not yet been programmed; publication or availability of tapes prior to 1984 is unlikely.† Any data derived from the 1970 Census must be used with caution.

(3) Contact with professional organizations and trade associations. Often the most precise and up-to-date employment figures can be obtained by contacting the organization representing a trade or profession.

The following references are useful in locating the relevant organization:

- Gale's Encyclopedia of Associations (Gale Research 1980)
- D.C. area telephone directories

The association staffer should be informed of the reason for the request, so that he or she can provide the most applicable estimate. Data limitations to be aware of include the possibility that retired or inactive members no longer involved in the occupation are still listed, or that the membership lists are simply out-of-date.

3.3.3 Enumeration of Site-Specific Populations

Exposure assessments requiring enumeration of workers at specific production facilities may be undertaken by using Method 3-4. This method relies on four sources of information:

1. Economic data (such as the Economic Information System - EIS - computerized data and printed reports)
2. The State Industrial Directories (State Industrial Directories Corp. 1979)
3. Direct contact with producers
4. State and federal OSHA inspection data.

---

†Personal communication between G. Hendrickson, Versar, and P. Vines, Bureau of the Census, December 1982.

Method 3-4. Enumeration of Site-Specific Populations

Option 1 (Direct Enumeration)

Step 1 Determine total employment at plant.

Option 1: Retrieve data from EIS. The Line-of-Business reports, available for major manufacturers, list the locations and total employment for facilities.

Option 2: Consult the State Industrial Directory. Facilities are listed by city in each state's volume.

Option 3: Directly contact the manufacturer.

Step 2 Estimate the proportion of total employees involved in production of the chemical in question.

Option 2 (Extrapolation of Sample Data)

Step 1 Retrieve OSHA inspection data for the chemical substance. Inspections will list the number of workers affected at each plant site.

Step 2 Calculate the average number of workers exposed per plant for each type of facility (production, processing, etc.).

Step 3 Multiply the average per plant by the total number of plants nationwide to enumerate the total occupational population.

Note: The limitations to the use of Option 2 are described in Section 3.3.3.

The method can use any or all of the sources above, but it is best applied to enumerating a limited number of populations; direct enumeration of this type may be expensive and time-consuming. While the data from these sources are reliable, it is often difficult to ascertain what proportion of workers in a large plant are involved in the production of the chemical substance of interest. Extrapolation of data from a few plants to obtain national employment estimates is possible. There are limitations to the use of sample data. Unless inspections are (1) representative of industry-wide conditions and (2) complete (i.e., all exposed workers in each plant were identified), data from extrapolation may be inaccurate. An additional problem is that the majority of inspections are several years old, and few OSHA inspections are now done each year.

The Economic Information System (EIS) is a comprehensive computer data base listing a company's facilities and the number of employees at each site. The data are, however, expensive to retrieve ($90 per hour online); the usefulness of the EIS is therefore restricted. Data can be obtained through the Control Data Corporation's Economic Business Information System (EBIS) or by phone or mail contact:

Economic Information Systems, Inc.
310 Madison Avenue
New York, N.Y. 10017
(212) 697-6080

The State Industrial Directories Corporation publishes a state-by-state listing of industrial facilities, arranged by city. The Directory is published annually and is available in major libraries. The level of detail reported varies by state; some states record total employment, while some distinguish between office and production workers and characterize the workers by sex. The data recorded in the Directory may, however, be incomplete since all information is supplied to the Corporation voluntarily (State Industrial Directories Corp. 1979).

States and smaller government units may also publish their own directories in an effort to attract business. State Departments of Commerce and local Chambers of Commerce are good sources of information. Contacting a producer directly, either by mail or telephone, often produces the most recent and detailed data on workers.

As mentioned previously, one production facility may process any number of chemicals. Knowledge of the total employment at that plant provides only an upper limit for estimating the exposed worker population. Assuming that production techniques for different chemicals are equally labor intensive, the following may provide an order-of-magnitude estimate of the number of workers involved in the production of one chemical:

$$\frac{PV_a}{PV_t} = \frac{E_a}{E_t}$$

where

PV_a = the production volume of the chemical being assessed

PV_t = total production at the facility

E_a = employees producing the chemical being assessed (the exposed population), and

E_t = total plant employment.

3.4 Characterization of Occupationally Exposed Populations

Method 3-5 summarizes the characterization of occupationally exposed populations. Physiological differences between workers of both sexes and various ages may affect chemical exposure or the resultant risk. The most recent data on the distribution of the work force between men and women are presented in Table 14; the relevant "percent of total employment" figures can be applied to the enumerated population.

Table 15 presents the age and sex distributions for major occupational groups. These data are based on the 1970 Census, however, and they should be used with caution. Economic and social evolution of the past decade has produced changes that are readily apparent to one who compares Tables 14 and 15. Women once accounted for less than 17 percent of the managers and administrators; in 1979, over 30 percent of that group were women.

The State Industrial Directory series discussed in Section 3.3.3 may also provide the number of male and female workers at specific locations, but those data are only collected for a few states.

Method 3-5. Characterization of Occupationally Exposed Populations

Step 1	Determine whether age and sex characterization or sex characterization is required.
Step 2	Characterize the population. Apply percent distributions to the enumerated population.

Option 1: (Age and Sex.) Consult Table 15 for data on general occupations. Be cognizant that data are 12 years old.

Option 2: (Sex only.) Consult Table 14 for 1979 data on general and specific occupations.

Option 3: (Sex only.) Consult data derived from site-specific sources (see Section 3.3.3).

Table 14. Employed Persons by Occupation and Sex, 1979

Occupation	Percent of total employment	
	Male	Female
Professional and technical workers	46.0	54.0
Medical and other health	25.2	74.8
Teachers except college	20.6	79.4
Other	64.5	35.5
Managers and administrators, non-farm	68.1	31.9
Salaried	67.5	32.5
Self-employed, retail trade	62.1	37.9
Other self-employed	78.6	21.4
Sales workers	45.9	54.1

4. POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES VIA THE INGESTION OF FOOD

4.1 Introduction

This section presents methods for enumerating and characterizing populations exposed to chemical substances via the ingestion of food. The methods described are applicable to food items or categories of foods that contain chemical substances as a result of (1) agricultural practices (e.g., use of pesticides, fertilizers), (2) processing (e.g., packaging, canning), (3) contaminants that can be traced to point, area, and line sources, and (4) contaminants of unknown origin detected via monitoring data.

The methods that follow rely in many cases on simplifying assumptions in order to enumerate the exposed populations; foods and food products have geographical distributions and processing patterns that fluctuate depending on seasonal demand and availability. Enumeration of the total consuming population for a specific food is a relatively straightforward process. The exposed population is, however, some fraction of the consuming population; that fraction is a function of the source of the chemical substance. The methods presented in this section can be used to estimate the range of the exposed population.

Figure 17 is a flow diagram of the three-stage framework for enumerating and characterizing populations exposed to chemical substances via the ingestion of food. Each stage is composed of several methods depending on the source of the exposure or how the exposed population is identified in the exposure assessment. Subsection 4.2 briefly describes the procedures for identifying the exposed population. The enumeration of the exposed population is the second stage and is discussed in Subsection 4.3. Subsection 4.3 is organized according to the source of the chemical substance as illustrated in Figure 17. The third stage, characterization of the exposed population by age and sex distribution, is the subject of Subsection 4.4. This stage would only be used if it were determined that a chemical substance had a specific effect on a particular age or sex group or that a particular group was more highly exposed.

Examples of the use of the methods in this section of the report are presented in Appendix A-3.

4.2 Identification of Exposed Populations

Exposed populations can be identified either through knowledge of the sources of chemical contamination or by examination of monitoring data.

Figure 17. Three-stage Framework for the Enumeration and Characterization of Populations Exposed to Chemical Substances via the Consumption of Food

The former is a "materials balance" approach and comprises three types of sources identifiable by an examination of a substance's use and release information:

1. Sources that result from agricultural practices (e.g., pesticide application, fertilization, growth hormones).
2. Sources related to processing and packaging procedures (e.g., contaminants introduced during canning, contaminants in food preservatives, leaching of contaminants from packing).
3. Other identifiable sources (e.g., ocean dumping, industrial effluents, contamination of animal feed during industrial processing).

Monitoring data may identify food items with contamination of unknown origin. The "Market Basket Surveys" of the Food and Drug Administration (DHEW 1975) are examples of monitoring data surveys that may identify contaminated food items, the consumers of which are the exposed population.

Comprehensive population identification must consider all three source types as well as available monitoring data. This identification will be conducted on a chemical-specific basis in the exposure assessment process. The general procedure for identification is presented in Method 4-1.

4.3 Methods for the Enumeration of Exposed Populations

Enumeration of the population eating a particular food item is straightforward; however, only a fraction of that population may consume contaminated food. Information on the geographic distribution of food items following harvest and packaging or processing is not available. Consequently, enumeration of the actual exposed population is not possible. Estimation of the population range in which the actual exposed population exists, however, is possible. The upper limit of the population range is equal to the total population that consumes a food item. The lower limit of the population range, based on the assumption that the consuming population is directly proportional to the quantity of the food item contaminated, can be estimated by multiplying the upper limit of the range by the percentage of the food item contaminated (e.g., the percentage of the food item grown in a particular geographic area, raised by a particular agricultural practice, processed or packaged by a particular procedure). The data bases and information sources that provide data and the methods to calculate the exposed population range are discussed in the following subsections according to the categories for identifying the exposed populations.

Method 4-1. Generalized Procedure for Identifying Populations Exposed to Chemical Substances via the Ingestion of Food

Step 1 Obtain all available monitoring data for the substance being assessed. Monitoring data for food items provide positive identification of exposure; the population that consumes the food item is an exposed population.

Step 2 Examine the uses of the substance being assessed. If it is used in an agricultural practice, the food items on which it is used may be contaminated. If it is used in a food processing procedure or in a packaging material, the food items processed or in contact may also be contaminated; the population that consumes the potentially contaminated food item is an exposed population.

Step 3 Examine the sources of the substance in the ambient environment. Knowledge of these sources, coupled with knowledge of the fate and transport of the substance in the environment, leads to the identification of the potentially contaminated food item; the population that consumes the food item is an exposed population.

4.3.1 Enumeration of Populations Exposed as a Result of Agricultural Practices

Enumeration of the population exposed to a chemical substance as the result of consuming a food item contaminated from an agricultural practice requires two steps. The investigator must first ascertain the size of the population that consumes the food item. This is the upper limit of the range of the exposed population. The percent of the total quantity of the food item that is produced via a specific agricultural practice must then be determined. This percentage multiplied by the number for the total consuming population yields an estimate of the lower limit of the range of the exposed population.

Values for the percent of the U.S. population that consumes a specific food item are available for some food items from the U.S. Department of Agriculture (USDA) Food Consumption Surveys. USDA Food Consumption Surveys are conducted approximately every 10 years. The most recent survey was in 1977-78, but the complete data reports for the 1977-78 survey have not yet been released. Therefore, the investigator must use data collected in the 1965-66 survey. Food Consumption of Households in the U.S., Seasons and Year 1965-66 (USDA 1972) presents data on food consumption by households in the 48 conterminous states for the period from April 1965 to March 1966. The percent of 15,112 households using selected food items for a seven-day period prior to the interview is presented.

The food items for which data are available represent a wide range of major food groups. The households surveyed were scientifically selected to represent a self-weighting sample of housekeeping households in each of four census regions during each of the four seasons. Excluded from the survey were those households in which no member ate as many as 10 meals from the household food supply during the seven days preceding the interview. Food Consumption of Households in the United States, Seasons and Year 1977-78, the most updated version of the 1972 USDA report, is expected to become available in mid 1983. Food Consumption of Households in the U.S., Spring 1977 (USDA 1982) presents preliminary data on food consumption of households in the 48 conterminous states during the period from April to June of 1977. Like the 1965-66 survey, this one presents the percent of 15,000 households using food items for a period of seven days prior to the survey. Unlike the survey of 1965-66 (USDA 1972), the survey of 1977-78 (USDA 1982) included households regardless of the number of meals eaten away from home.

Information used to obtain values for the percent of a food item produced via a specific agricultural practice or in a specific geographic area is available for select food items from two data sources. The 1978 Census of Agriculture, U.S. Summary (Bureau of the Census 1982a) presents statistics for the leading states and counties for select agricultural products based on data obtained from the Census of Agriculture. More detailed information was obtained for farms with sales of $2,500 or more than for farms with less gross sales. Statistics on value of agricultural products sold, number of acres harvested, and quantity harvested are included.

Agricultural Statistics 1978 (USDA 1978) also presents data for production and value of select agricultural products and utilization (e.g., fresh, frozen, canned, dried) of quantities sold. Some statistics for states are included. If the quantity of a food item harvested from a specific geographic region is desired and is not included in either of these two sources, the information, if available, can be obtained by contacting the Statistical Reporting Service-Crop Reporting Board of the United States Department of Agriculture ((202) 447-4020).

The basic steps for enumerating populations exposed to chemical substances via the ingestion of food contaminated by some form of agricultural practice is presented in Method 4-2. The approach can be used for virtually any situation.

4.3.2 Enumeration of the Populations Exposed as a Result of Processing and Packaging

The procedures for enumerating the population exposed to a chemical substance as a result of consuming a food contaminated during processing and packaging are similar to the procedure discussed in Section 4.3.1. If a food is contaminated during a processing procedure (e.g., canning, freezing, drying), the investigator must determine the percent of the U.S. population that consumes the processed food item. This percentage is multiplied by the total 1980 U.S. population to determine the consuming population. If the chemical substance contaminating the processed food is generic to all methods for producing the processed food item, then the exposed population is equal to the consuming population. If, however, the chemical substance is specific to only certain methods, then the consuming population is the upper limit of the range of the exposed population. To determine the lower limit of the range of the exposed population, the investigator must determine the fraction of the food that undergoes the specific processing method; this fraction is multiplied by the consuming populations.

Method 4-2. Enumeration of Populations Exposed as a Result of Agricultural Practices

Step 1 Determine the percentage of households that consume a specific food item by consulting Food Consumption of Households in the U.S., Spring 1977 (USDA 1982). Statistical evaluation of seasonal data by USDA (1972) indicates that household food consumption at home in the spring is more representative of average consumption during the year than is consumption in the summer, fall, or winter. Food Consumption of Households in the U.S., Seasons and Year 1977-78, the best information source, will be published in mid 1983.

Step 2 Multiply the percentage determined in Step 1 by the total U.S. resident population in 1980 of 226,500,000 (Bureau of the Census 1982b) to calculate the consuming population or the upper range of the exposed population.

Step 3 Define the contaminated area by county, and determine the percentage of the total quantity of the food item harvested from the geographic area subjected to the agricultural practice by consulting the 1978 Census of Agriculture (Bureau of the Census 1982a) and Agricultural Statistics (USDA 1978). If the information needed is not in this report, contact the USDA, Statistical Reporting Service - Crop Reporting Board ((202) 449-4020).

Step 4 Multiply the fraction derived in Step 3 by the value calculated for the consuming population in Step 2. The resulting value is the estimated lower limit of the exposed population.

The technique for enumerating the population exposed to a chemical substance in food as a result of packaging is the same as that discussed for exposure from processing. The consuming population (i.e., the upper limit of the exposed population) is estimated first. The investigator determines what fraction of the food undergoes a specific packaging procedure and then multiplies that fraction by the population estimated to consume the food item to estimate the lower limit of the range. The following paragraphs discuss the sources of information for the data needed to perform these calculations.

The report Food Consumption of Households in the United States, Spring 1977-78 (USDA 1982) should be used to obtain values for the percentage of the U.S. population that consumes select food items. This data source has been discussed in detail in the previous subsection. This report also includes data on processed food consumption for select food items (e.g., canned peas, frozen peas, powdered milk).

There is no comprehensive source of data reporting the percentage of specific methods and chemicals for processing or packaging materials for specific foods and beverages (e.g., the percentage of meats processed with or without nitrites; the percent of frozen broccoli packaged in cardboard vs. that packaged in plastic film). This information may be available from the trade association corresponding most closely to the food item or packaging procedure in question. For a comprehensive listing of trade associations, consult the most recent issue of the "Encyclopedia of Associations" published by Gale Research, Inc. The procedural steps to enumerate populations exposed to a chemical substance via the ingestion of food contaminated by processing and packaging are presented in Method 4-3.

In some instances, the contamination from processing or packaging of a specific food item may result from procedures used by a specific company. The number of people that consume a specific brand of food or beverage can be estimated for select foods and beverages from the Simmons Media Studies Volumes on Food and Food Marketing, Alcoholic Beverages, and Carbonated Soft Drinks and Pet Food (SMRB 1977). EPA-OTS is in the process of acquiring the latest Simmons Market Research Bureau (SMRB) reports. Volumes for 1976-77 are available in the Washington, D.C. area at the George Mason University Library.

The SMRB studies are designed to make it possible for advertisers and agencies to assess the relative values of media in terms of marketing potential for over 500 product and service categories and 3,000 individual brands. The studies present demographic and lifestyle characteristics, media habits, and product use, based on data collected from one of the largest annual national consumer probability samples taken. Respondents are selected to represent the conterminous U.S. population 18 years of age and older. It should be noted that, for most food items listed, the number of users is based on the total U.S.

Method 4-3. Enumeration of Populations Exposed as a Result of Packaging and Processing of Food

Step 1	Determine the percentage of users of the food from Food Consumption of Households in the U.S. Spring 1977 (USDA 1982). This report contains values for both processed and unprocessed foods.
Step 2	Multiply the percentage (i.e., fraction) obtained in Step 1 by the U.S. population in 1980 of 226,500,000 (Bureau of the Census 1982b) to estimate the consuming population. This is the upper limit of the exposed population. If the chemical substance is generic to all methods for producing the processed food, then the exposed population is equal to the total consuming population.
Step 3	If a chemical substance is introduced to a food item (1) via a specific method for processing or (2) from a packaging procedure or material, investigators must determine what portion of total production for that food item is affected. These data may be difficult to obtain. Food Consumption on Households in the U.S. Spring 1977 (USDA 1977) provides data on the percentage of users of food items prepared by such processes as canning, drying, and freezing. Trade associations that are related to the food item may have this information. Processing and packaging associations (e.g., National Food Processors Association, Washington, D.C.) may also have this information. For a comprehensive listing of trade associations, consult the most recent issue of the "Encyclopedia of Associations" published by Gale Research Corp.
Step 4	Multiply the total consuming population estimated in Step 2 by the percentage determined in Step 3 to estimate the lower limit of the range of the exposed population. If no information on the percentage of the food item packaged or processed by the method causing contamination is obtained in Step 3, the upper limit estimated in Step 2 should be used; however, it should be clearly labeled as a possible overestimate.

population of female homemakers (the buyers of the food) and not the total U.S. population 18 years of age and older. The data, however, can be used to approximate household use. Section 5 of this volume, Populations Exposed to Chemical Substances via the Use of Consumer Products, provides greater detail on the use of SMRB data.

To enumerate the population exposed as a result of consuming food contaminated by processing or packaging procedures used by a specific company, the general approach described in Method 4-4 should be used. In some cases, data will be reported only for the female homemaker. To extrapolate for the total consuming population, investigators should (1) refer to SMRB data (which provide the number of persons in the buyer's household) or (2) use a generic multiplication factor of 2.73 persons per household (Bureau of the Census 1982c).

4.3.3 Enumeration of Populations Exposed as a Result of Releases from Other Sources

This category includes all forms of food contamination that are not the result of either an agricultural practice or a processing and packaging procedure. This section concentrates principally, however, on chemical substances introduced as a result of accidents (e.g., introduction of PBB to cattle feed in Michigan) and from point source airborne or waterborne effluents (fish contaminated from industrial discharges, airborne particulates deposited on fruits and vegetables). The source of the chemical substance need not be identified. The methods in this section also apply to foods from geographically defined areas of contamination which have been identified from monitoring data. This special case is discussed in Subsection 4.3.4.

The procedure for enumerating the population exposed to a chemical substance as the result of consuming a food item contaminated from such sources is similar to the procedures previously discussed. The investigator must first determine the percent of the U.S. population that consumes the food item. This percentage is applied to the total 1980 U.S. population to determine the total consuming population. Next, the percent of the total quantity of the food item in the U.S. from the geographic area affected by the source of contamination must be ascertained. The product of the total consuming population and the percent of the food item affected by the source provides an estimate of the lower limit of the exposed population.

Four basic food groups may be affected by these sources of contamination: agricultural products, freshwater fish and game, seafood, and home grown foods. The method used to enumerate the exposed population is different for each of these basic food groups.

(1) Agricultural products. To enumerate the U.S. population exposed to a chemical substance as a result of consuming a contaminated agricultural product, the investigator should use the method for enumerating the population exposed as a result of agricultural practices

Method 4-4. Enumeration of Populations Exposed as a Result of Packaging or Processing Procedures Used by a Specific Company

Step 1 Identify the affected brand of food, and obtain use data from the Simmons Market Research Bureau reports (SMRB 1977). Users may be reported as total adults or female homemakers.

Step 2 Estimate the total consuming population for the food brand.

Option 1 - The average number of persons per household is 2.73. Assuming that there is one food shopper per household, multiply the total number of buyers by 2.73 to calculate the exposed population.

Option 2 - Simmons data are aggregated by the number of persons in a user's household. (This is fully discussed in Section 5.3.1 of this report.) The calculation is performed as follows:

1 person household = number of buyers x 1 = A
2 person household = number of buyers x 2 = B
3-4 person household = number of buyers x 4 = C
5 or more person household = number of buyers x 6 = D

A + B + C + D = total exposed population (estimated conservatively).

(see Method 4-2, described in Section 4.3.1). Instead of determining the percent of the total quantity of the food item harvested from the geographic area subjected to the agricultural practice (Step 3), determine the percent of the food from the geographic area that has been contaminated.

(2) Noncommercial fish and game. To enumerate the U.S. population exposed to a chemical substance as a result of consuming contaminated freshwater fish or game, the investigator can use information from the fish and game commission of the state in which the contaminated area is located. The sample population for these surveys comprises hunters and fishermen who have purchased licenses from the state conducting the surveys. Based on information from the few states contacted, most states conduct surveys of this nature about every five years. An example of the type of survey information that may be pertinent is the summary of applicable categories of results included in the 1975 Fishing Survey conducted by the State of West Virginia (West Virginia DNR 1979). These categories include:

1. Estimated number of fishermen and days fished by type of fishing.
2. Estimated number of fishermen and days fished by district (WVA DNR) fished and type of fishing.
3. Estimated number of fishermen and days fished by river system and major river.
4. Estimated number of fishermen and days fished in lakes and impoundments.

To enumerate the population exposed to a chemical substance as a result of consuming noncommercial freshwater fish or game contaminated, from an identified source, the investigator should use Method 4-5. The estimated exposed population obtained in Step 1 of this method underestimates the actual exposed population because it represents the number of licensed hunters or fishermen in a defined geographic area and does not include all the consumers of the fish or game (such as friends and family members). If it is assumed that each license represents a household, the exposed population can be estimated, as presented in Step 2, by multiplying the number of licenses by 2.73, the average number of persons per household (Bureau of the Census 1982c).

(3) Commercial fish and shellfish. To enumerate the population exposed as a result of consuming seafood contaminated by releases from an identified source, one must determine the percent of the U.S. population that consumes the food item. The percent of the total quantity of the food item from the geographic area affected by the source of contamination must also be ascertained.

Method 4-5. Enumeration of Populations Exposed as a Result of Consuming Noncommercial Freshwater Fish or Game from a Geographically Defined Area of Contamination

Step 1	Obtain the number of licensed fishermen or hunters reported to fish or hunt in the geographically-defined area of contamination by contacting the state fish or game commission. The best source of this information is usually the most recent fish and game survey conducted by the state fish and game commission.
Step 2	Estimate the upper limit of the actual exposed population by assuming that each licensed fisherman or hunter represents a consuming household. Since there are 2.73 persons in the average household (Bureau of the Census 1982c), a rough estimate of the actual exposed population can be calculated by multiplying 2.73 by the number of licensed hunters or fishermen obtained from Step 1.

Values for the percent and projected number of individuals in 1980 who consume the 45 most commonly eaten species of seafood are available in the Report to the National Marine Fisheries Service on Seafood Consumption Patterns by NPD Research Inc. (NPD 1977). Table 16 summarizes the statistics on seafood consumption compiled by NPD (1977).

The quantity of the food item from the geographic area affected by the source of contamination can be obtained from a computerized data base maintained by the National Oceanic and Atmospheric Administration (NOAA) for all states except Maryland. The NOAA data base includes catch records by NOAA area or by county for oysters, finfish, and crabs. Catch records for clams are available only for descriptive areas such as "Mouth of the Patuxent River." Catch records for clams, oysters, and finfish are available in the form of daily records for the years 1975 through 1981. Catch records for crabs are available only for 1981. For information on retrieving data from the NOAA computerized data base, contact Daryl Christensen of the National Marine Fisheries Service at (201) 872-0200. For retrieval of data on seafood catches for the Chesapeake Bay, contact Mike Burch of the Statistics Division of the Maryland Department of Natural Resources at (301) 269-3784. There is no charge to government agencies for either of these services.

For information on the total quantity of seafood species caught in the United States, the statistics on commercial fishery landings published in Fisheries of the United States, 1980 by the National Marine Fisheries Service of NOAA (NOAA 1981) can be used.

The general approach for enumerating the population exposed to a chemical substance as a result of consuming seafood contaminated by releases from an identified source is presented in Method 4-6.

Table 16 includes a few freshwater fish species. Method 4-6, however, cannot be used to enumerate the population exposed as a result of consuming these fish species. To obtain such information, investigators must ascertain the quantity of freshwater fish caught annually from the geographically defined area of contamination. Although the quantity of select seafood items caught from a geographically defined area of contamination can be obtained from computerized NOAA data, no similar data base for freshwater fish was found.

(4) Home grown fruits and vegetables. In 1977, it was estimated that 44 percent of U.S. households (32 million households) had home gardens (USEPA 1980). Furthermore, 80 percent of these 32 million households had gardens every year, and 40 percent of these 32 million households had had gardens for 11 years or more. The consumption of home grown foods, therefore, may be a significant route of exposure, both short- and long-term, if the garden is located near a point source of contamination, such as a smelter.

Table 16. Ranking of Seafood Species by Percent of Individuals Consuming and Projected 1980 Consuming Population

Rank	Species	Number of users	Percent of sample size	Projected number of total 1980 population (X 1,000)
	Total sample	25,947	100.0	226,000
	Total seafood	25,165	94.0	204,000
1	Tuna, light	16,817	64.8	146,000
2	Shrimp	5,808	22.4	50,600
3	Flounders	3,327	12.8	28,900
4	Ocean Perch	2,519	9.7	21,900
5	Salmon	2,454	9.5	21,500
6	Clams	2,242	8.6	19,400
7	Cod	1,492	5.6	12,700
8	Pollock	1,466	5.6	12,700
9	Haddock	1,441	5.6	12,700
10	Herring	1,251	4.8	10,800
11	Oysters	1,239	4.8	10,800
12	Crab, other than King	1,168	4.5	10,200
13	Trout (Freshwater)	970	3.7	8,360
14	Catfish (Freshwater)	876	3.4	7,680
15	Bass	826	3.2	7,230
16	Lobster, Northern	675	2.6	5,880
17	Mackeral, Other than Jack	616	2.4	5,420
18	Halibut	574	2.2	4,970
19	Scallops	526	2.0	4,520
20	Whitefish	492	1.9	4,290
21	Snapper	490	1.9	4,290
22	Hake	392	1.5	3,390
23	Pike	390	1.5	3,390
24	Lobster, Spiny	350	1.3	2,940
25	Smelt	328	1.3	2,940
26	Perch (Freshwater)	268	1.0	2,260
27	Bluegills	265	1.0	2,260
28	Bluefish	236	0.9	2,030
29	Crappie	228	0.9	2,030
30	Trout (Marine)	220	0.8	1,810
31	Bonito	148	0.6	1,360
32	Crab, King	130	0.5	1,130
33	Mullet	97	0.4	904

Method 4-6. Enumeration of Populations Exposed as a Result of Consuming Seafood from a Geographically Defined Area of Contamination

Step 1 Determine the number of users of the seafood by consulting the information in Table 15 on projected number of individuals in 1980 who consumed the seafood item of concern.

Step 2 Determine the percentage of the total quantity of the item caught for sale in the U.S. which is from the geographically defined area of the source of contamination. This can be accomplished by computing the quantity of the seafood caught annually from the geographically defined area of contamination based on computerized NOAA data. Next, the total quantity of the seafood species caught in the United States annually must be obtained from commercial fishery landings published in *Fisheries of the United States, 1980* (NOAA 1981). The fraction of the total quantity of the seafood species caught for sale in the U.S. which is from the geographically defined area of the source of contamination can be computed by the following formula:

$$\frac{\text{quantity of the seafood item caught from the geographically defined area of contamination}}{\text{total quantity of the seafood item caught in the United States}}$$

Step 3 Multiply the fraction computed in Step 2 by the value determined for the consuming population determined in Step 1.

Table 17 presents data for the year 1977 on the percent of urban, rural non-farm, and rural farm households with gardens as well as the percent of the U.S. population for each category. These geographic categories are consistent with the census geography of the Bureau of the Census. Table 18 presents data on the percentage of total households growing, freezing, canning, or preserving selected home grown fruits and vegetables. The data presented in these two tables can be used to enumerate local populations exposed to a chemical substance via the consumption of inadvertently contaminated home grown fruits and vegetables. Method 4-7 presents that procedure.

4.3.4 Enumeration of Exposed Populations by the Use of Monitoring Data

The source of contamination of a food item will frequently be unknown. The fact that contamination exists, however, can be positively confirmed through monitoring data collected. Market Basket Surveys such as those conducted by the Food and Drug Administration (DHEW 1975) exemplify how food contamination can be detected. The consumers of the food item in which the substance has been detected are the exposed population.

Monitoring data can be used to predict the number of people consuming foods containing a chemical substance. The method extrapolates data on the frequency of detection of the substance. The accuracy achieved by this tool depends on the form, representativeness, and sample size of the data. The procedure for enumerating population by use of monitoring data is presented in Method 4-8.

The assumptions inherent in this very gross estimation include the assumption that the data are independent of the source of the contamination or that the data represent the total food supply from all geographic areas. Obviously, these assumptions limit the usefulness of the method; it should only be used in the absence of more refined data.

The use of monitoring data to estimate the exposed population is limited in all cases by two assumptions. The sample size must be large enough that the frequency of detection approximates the frequency of occurrence, and individuals who consume food containing the chemical at levels below the detection limit are not included in the exposed population. Exposure below the detection limit may, however, be significant for certain chemicals.

Table 17. Percent of Households, U.S. Population, and Household Size in Urban, Rural Non-Farm, and Rural Farm Areas with Home Fruit and Vegetable Garden in 1977

Urbanization	Percent households with garden	Household size (number of persons)	Percent of total U.S. population
Urban	43	3.17	32
Rural non-farm	41	3.44	9
Rural farm	84	3.86	3

Method 4-7. Enumeration of Populations Exposed to Chemical Substances via the Consumption of Home Grown Fruits and Vegetables

Step 1 Identify the geographic area contaminated from the source of the chemical substance (e.g., industrial point source, area source).

Step 2 Determine the number of households in the geographic area from General Population Characteristics, Series PC80-1-B (Bureau of the Census 1982b).

Step 3 Multiply the number of households obtained in Step 2 by the percent of households with home fruit and vegetable gardens for the type of urbanization from Table 16. This is the number of households with fruit and vegetable gardens in the area contaminated, the inhabitants of which are the potentially exposed population.

Step 4 Enumerate the exposed population by multiplying the number of households from Step 3 by the household size for the degree of urbanization also available in Table 16.

Step 5 Steps 3 and 4 determined the number of households and individuals that have fruit and vegetable gardens, not the households that grow a specific type of food. If the chemical substance is absorbed by a specific food item, the data in Table 17 can be used. For example, if a pollutant is absorbed specifically by lettuce, the number of households for each population category estimated in Step 3 must be multiplied by 51 percent, the percentage of gardening households that grow lettuce according to the latest available data. These results should then be multiplied by household size (Table 16) to enumerate the exposed population.

Method 4-8. Enumeration of Exposed Populations by the Use of Monitoring Data

Step 1	Identify the food items contaminated as a result of the monitoring survey results.
Step 2	Enumerate the total consuming population for each of the food items identified. The enumeration procedures of Methods 4-2, 4-5, 4-6, or 4-7 should be used to estimate the consuming population. This is the upper limit of the range of the exposed population (i.e., all consumers of the food item eat some contaminated food).
Step 3	Calculate the frequency of detection from the monitoring data; if detected in 10 of 100 samples, the detection frequency is 10 percent.
Step 4	Multiply the detection frequency by the total consuming population as enumerated in Step 2 to estimate the exposed population. This is the lower limit of the range of the exposed population (i.e., the exposed population consumed only contaminated food).

4.4 Characterization of the Exposed Population

This subsection describes the data sources and procedures for characterizing the exposed population with respect to age and sex. In most exposure assessments, age and sex characterization will not be necessary. If, however, the chemical substance of interest has special effects on particular age classes such as children or the elderly, further characterization of the enumerated population is indicated. If a chemical substance is determined to be teratogenic, enumeration of women of child bearing age may be required. Age and sex also influence the average rate of food intake and the types of food consumed. Construction of a plausible worst-case exposure scenario for contaminated food may, for instance, focus on males 19 to 22 years of age; they have the highest average daily food intake rate (USDA 1980).

The simplest and most rapid method of characterizing a large population is to assume that the age and sex distributions approach those of the total U.S. population. This approach can be used only for very large, generally-defined populations. For example, the population consuming the typical "American Diet" or those who consume groups of major food categories approximate the national distribution. The age and sex distribution by percentage of the total U.S. population has been presented in Table 12 of Section 2.4 of this report (Characterization of Populations Exposed to Chemical Substances in the Ambient Environment). The characterization of populations exposed to chemical substances through the consumption of particular food items, however, often requires a much more accurate approach; the defined food preferences vary greatly according to particular age and sex, and even by sex within age classes.

There are two data sources for characterizing populations exposed to chemical substances via food consumption: USDA's food consumption surveys for individuals and the Simmons Market Research Bureau reports. The USDA data are applicable to populations eating various types of food, while SMRB marketing information is useful for characterizing consumers of specific brands of foods.

The individual food consumption surveys conducted by USDA were designed to be representative of the U.S. population. As a result, the age and sex distribution of the sampled population closely approximates that of the U.S. as a whole. Data on usage are reported for various age and sex groups, as illustrated in Figure 18, as percentages of the total sample within that group. Percents reported under the column heading for the food of interest can be applied directly to the total U.S. population for that age/sex classification to characterize the exposed population. Method 4-9 presents the steps to be performed for this type of characterization.

Figure 18. Example Data Summary from National Food Consumption Survey of 1977-78

Method 4-9. Characterization of Populations Exposed to Chemical Substances in Types of Food

Step 1 Locate the food item usage data in the USDA (1972, 1980) food consumption surveys for individuals in one day. The more recent (1980) data should be used whenever possible.

Step 2 Apply the "percent using" value for each age/sex category to the corresponding total population in that category (from Table 13).

Step 3 Compare "percent using" for the total sample as reported in the one-day survey to the "percent using" reported in the USDA (1982) one-week household consumption survey. This comparison will provide a qualitative indicator of the one-day survey's accuracy. If the data values are significantly different (i.e., the individual consumption data in USDA (1972, 1980) underestimates the consuming population), the total consuming population should be estimated using household data (USDA 1982) as presented in Step 1 of Method 4-2. The percentage of the total consuming population that is in the age or sex group of interest should be determined from the individual survey data (USDA 1972, 1980). This is calculated by aggregating the consumers for each age or sex class and dividing by the total consuming population of the individual sample. This percentage should then be applied to the total consuming population determined from the household data to characterize the exposed population (See Appendix A-3, problem 7).

Though the sample population is representative of the age and sex distribution of the U.S. population, a limitation inherent in the one-day survey biases the data. Consumption during one day may not be representative of normal eating patterns; this generally results in an underestimate of the number of consumers of specific foods. The one-day survey is, however, the only source of consumption data that presents the information by age and sex. Method 4-9 provides an approach to determine the accuracy of the individual consumption data and a procedure that can be used to eliminate the error.

Age and sex distributions of populations that consume specific brand names of food can be derived from the Simmons Market Research Bureau Reports. The most recent version of this report is available in EPA-OTS. Reports for the years 1977 through 1978 are available in the Washington, D.C., area at the George Mason University Library. SMRB reports present demographic data for most major brand name food items.

Section 5 of this report discusses the use of SMRB data to characterize populations using consumer items; that discussion is equally relevant to food consumption. In essence, SMRB presents information on the frequency that sample households include children within certain age groups. The ages of the adults in the household are similarly reported as frequencies. A general age distribution can thus be compiled easily for any item; the proportion of males and females can be assumed.

5. POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES VIA THE USE OF CONSUMER PRODUCTS

5.1 Introduction

This section presents methods for enumerating and characterizing populations exposed to chemical substances via the use of consumer products. The methods described are applicable to new and existing substances in consumer products. Figure 19 is a flow diagram of the three-stage method framework. Included in the diagram are some of the major data sources used.

The identification of the exposed population is discussed only briefly in this report (Subsection 5.2). The process is straightforward and relies primarily on materials balance information and data generated by the consumer exposure assessment methods report (Volume 7).

Enumeration of exposed populations may involve one or more steps and a variety of data sources. Subsections within Section 5.3 describe the sources of data applicable to enumeration of consumers and methods for utilizing and refining available data.

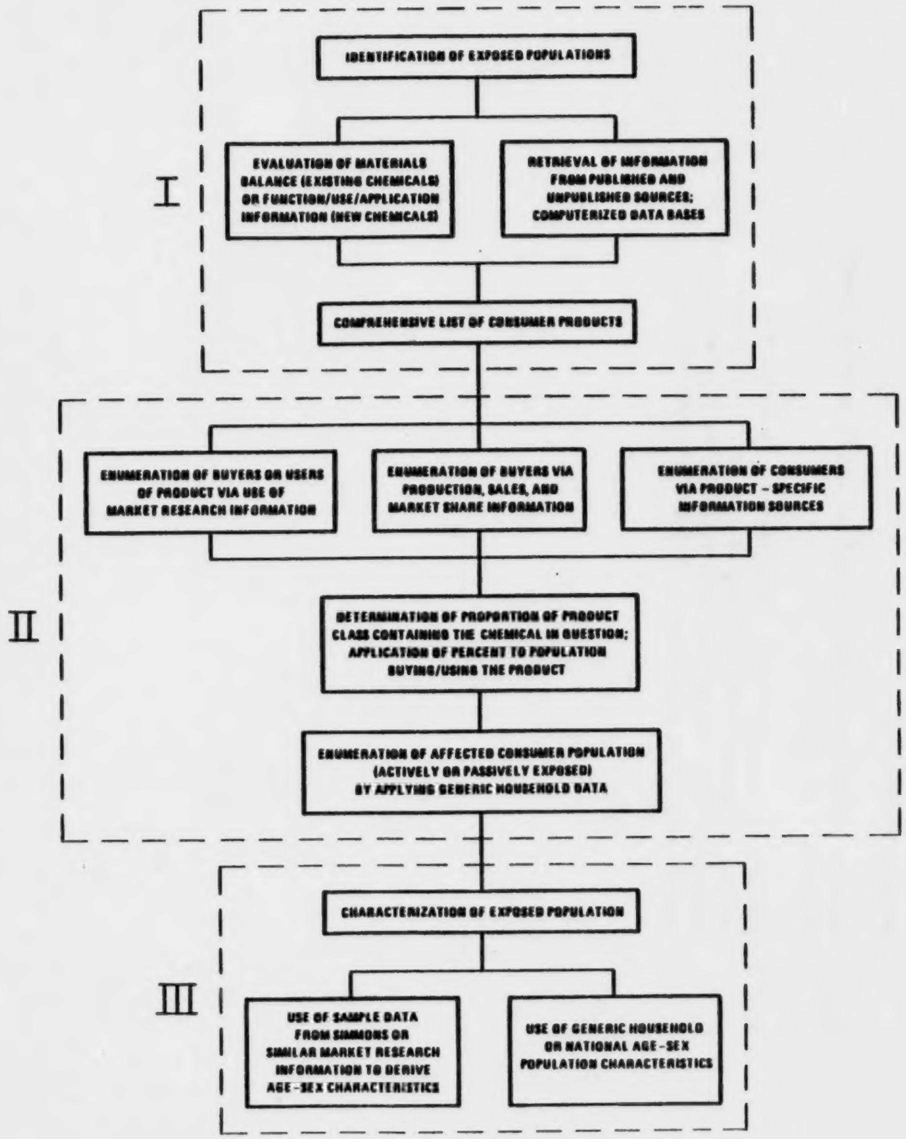
The age and sex of the exposed consumers affect the physiological parameters (i.e., breathing rate, skin surface area) that determine exposure; they also identify sensitive subpopulations (e.g., women of child-bearing age). Detailed exposure assessments may require that populations be described by age and sex distribution. Subsection 5.4 discusses methods of characterizing exposed consumer populations.

Examples of the use of the methods in this section are presented in Appendix A-4 of this report.

5.2 Identification of Exposed Populations

The identification of populations exposed to chemical substances via the use of consumer products (Method 5-1) necessitates a listing of all products containing the chemical in question. The information needed to compile such a list is derived from the materials balance for existing chemicals, from information submitted by Premanufacturing Notice (PMN) petitioners, and through literature searches.

Exposure assessments for most existing chemicals include a materials balance delineating the uses for that chemical, as well as the amount going to each use. A PMN submittal provides the corresponding information for new chemicals. PMNs are, however, usually incomplete; use information is often general, and not all the potential uses of a new chemical will be considered. Volume 7 of this series (methods for assessing consumer exposure to chemical substances) presents methods to predict uses for new chemicals.



IDENTIFICATION OF EXPOSED POPULATIONS
EVALUATION OF MATERIALS BALANCE (EXISTING CHEMICALS) OR FUNCTION/USE/APPLICATION INFORMATION (NEW CHEMICALS)
RETRIEVAL OF INFORMATION FROM PUBLISHED AND UNPUBLISHED SOURCES; COMPUTERIZED DATA BASES
I
COMPREHENSIVE LIST OF CONSUMER PRODUCTS
ENUMERATION OF BUYERS OR USERS OF PRODUCT VIA USE OF MARKET RESEARCH INFORMATION
ENUMERATION OF BUYERS VIA PRODUCTION, SALES, AND MARKET SHARE INFORMATION
ENUMERATION OF CONSUMERS VIA PRODUCT - SPECIFIC INFORMATION SOURCES
II
DETERMINATION OF PROPORTION OF PRODUCT CLASS CONTAINING THE CHEMICAL IN QUESTION; APPLICATION OF PERCENT TO POPULATION BUYING/USING THE PRODUCT
ENUMERATION OF AFFECTED CONSUMER POPULATION (ACTIVELY OR PASSIVELY EXPOSED) BY APPLYING GENERIC HOUSEHOLD DATA
CHARACTERIZATION OF EXPOSED POPULATION
III
USE OF SAMPLE DATA FROM SIMMONS OR SIMILAR MARKET RESEARCH INFORMATION TO DERIVE AGE-SEX CHARACTERISTICS
USE OF GENERIC HOUSEHOLD OR NATIONAL AGE-SEX POPULATION CHARACTERISTICS

Figure 19. Three-stage Framework for the Identification, Enumeration and Characterization of Populations Exposed to Chemical Substances in Consumer Products

Method 5-1. General Procedure for Identifying Populations Exposed to Chemical Substances in Consumer Products

Step 1 Compile a comprehensive list of the consumer products known to or thought to contain the chemical substance by consulting the materials balance or PMN submittal.

Step 2 Determine whether all or a portion of the consumer product class contains the chemical; if possible, identify by brand name to expedite enumeration.

Step 3 Identify products obviously intended for use by males or females or specific age groups.

Step 4 Evaluate each product (using the guidelines in Volume 7 of this series) to determine whether passive exposure is of concern. Consumer product use patterns will identify the passively exposed population (i.e., family or household members).

Many types of consumer products are of varied formulation, and only a fraction of the product class (perhaps identifiable by brand name) may contain the chemical substance. This fact should be established during the population identification phase. For example, formaldehyde is used in some shampoos as a preservative; in order to define and enumerate the population exposed to formaldehyde in shampoo, one must determine what fraction or brands of the product class (shampoo) contain the chemical (formaldehyde). Methods for that purpose are presented in Subsection 5.3.

Some products may cause exposure not only to the user (active exposure) but also to others in the vicinity (passive exposure). Volume 7 presents some guidelines for identifying products that may cause passive exposure. Generally, passive exposure to consumers results from the use of household or personal care products; the passively exposed population is the household of which the user is a member. Subsequent sections address the concept of enumerating those passively exposed in households.

5.3 Methods for the Enumeration of Exposed Populations

The effort required to enumerate consumers exposed to a particular product depends on two factors: (1) the availability of data specific to that product and (2) whether both active and passive exposure to the substance are involved. The following subsections guide the assessor in obtaining the available data and present methods for their use.

5.3.1. Enumeration of Exposed Populations via Simmons Market Research Bureau Reports

Simmons Market Research Bureau (SMRB) is a market research corporation that collects information on the buying habits of the population through questionnaires administered to a nationwide panel of consumers. The Simmons studies, "Selective Markets and the Media Reaching Them" (SMRB 1982), are designed to serve retailers, advertising agencies, and the media by providing up-to-date, comprehensive information on current and potential sales markets of consumer products.

SMRB data applicable to enumerating exposed consumer populations are contained in 29 volumes organized by product category. Table 19 lists the 29 product categories. These volumes contain information on market share, the number of buyers, and buyer demographics for over 500 consumer products. Table 20 is an alphabetical index of individual products and services investigated by SMRB.

Table 19. Simmons Market Research Bureau Product Categories and Services Provided by Volume

Volume Number	Volume Title
P-1	Automobiles
P-2	Cycles, Trucks, Vans & Tires
	Automotive Products & Services
P-4	Travel
P-5	Banking Investments, Memberships & Public Activities
P-6	Insurance & Credit Cards
P-7	Books, Records, Tapes, Stereo & TV
P-8	Appliances, Sewing & Garden Care
P-9	Home Furnishings & Home Improvements
P-10	Sports & Leisure
P-11	Restaurants, Stores & Grocery Shopping
P-12	At Home Shopping, Yellow Pages, Florists & Telegrams
P-13	Jewelry, Wristwatches, Luggage & Men's Apparel
P-14	Women's Apparel
P-15	Tobacco Products & Photography
P-16	Distilled Spirits & Mixes
P-17	Malt Beverages & Wine
P-18	Coffee, Tea, Soft Drinks, Juices & Bottled Water
P-19	Dairy Products, Spreads, Cookies & Desserts
P-20	Cereals, Rice, Pasta, Pizza, Fruits & Vegetables
P-21	Soup, Meat, Fish, Condiments & Dressings
P-22	Chewing Gum, Candy & Snacks
P-23	Soap, Laundry & Paper Products & Kitchen Wraps
P-24	Household Cleaners, Room Deodorizers & Pet Foods
P-25	Health Care Products & Remedies
P-26	Oral Hygiene Products, Skin Care & Deodorants
P-27	Hair Care & Shaving Products
P-28	Women's Beauty Aids, Cosmetics & Personal Products
P-29	Games & Toys, Children's & Babies' Apparel & Specialty Products
P-30	Relative Volume of Consumption

Source: SMRB 1982.

Source: Reprinted from SMRB 1982.

The information provided for each product in each volume is divided into three sections: usage, types, and brands. In each section, demographic information on the buyer of the product is presented: age, race, employment, education, place of residence (i.e., metropolitan central city, metropolitan suburban, and non-metropolitan), income, and household occupant characteristics. Usage of products by individuals and households is subdivided into "heavy," "medium," or "light." Table 21 lists an example of a hypothetical product usage calculation as performed by SMRB. The "heavy," "medium," and "light" designations are not absolute. They are based on the relative frequency of use of each product; the designations therefore vary from product to product. The usage rates are defined by SMRB for each product, and a table such as Table 21 is generated for each SMRB product. This information is particularly valuable for enumerating populations that may have high, medium, or low exposure to chemical substances via the use of consumer products when the same usage rates for product consumption are used to predict exposure levels. Table 22 is a sample table of SMRB usage data for rug cleaners. SMRB also presents the same demographic data according to product types (e.g., a rug cleaner may be marketed as a liquid, an aerosol, or a powder). Table 23 is a sample table of SMRB data for different types of rug cleaners purchased by female homemakers. Finally, SMRB also presents demographic data for specific name brands of products. Table 24 is a sample table of SMRB data for different name brand rug cleaners purchased by female homemakers.

SMRB presents data according to the characteristics of the buyer only. For example, for many consumer products the principal purchaser (as determined by the SMRB national consumer panel) may be the "female homemaker."* SMRB therefore only presents data for that product for the female homemaker. Six population groups are assumed to represent principal purchasers: adults, males, females, professional/managerial, female homemakers, and mothers. Furthermore, SMRB only reports data for populations 18 years of age and older. The implications of these factors cannot always be quantified.

Users of a product can be enumerated as the total number of users, or they can be disaggregated by brand or type of product. Figure 20 illustrates the SMRB presentation of data on usage of toothpaste by females. The first number in Column A under "all users" indicates that 75,174,000 females use toothpaste; this represents 92.7 percent of all

---

* The term "female homemaker" is defined by SMRB as adult women who assume responsibility for the maintenance of a household. The term includes working women and women living alone as well as in families, and represents over 90 percent of adult women. It should be recognized that products bought and used by female homemakers are often purchased and used by males maintaining households. SMRB does not adjust for this limitation; resultant population data may therefore be somewhat underestimated.

Table 21. Product Usage Categorization for SMRB "Heavy," "Medium," and "Light" Designations

Number used in household in last 7 days[a]	HML[b] designation	Assigned weight x	Product users (X1000[c]) =	Weighted consumption (X1000)	Percent of consumption	Percent of users[d]
10 or more	H	10.0	5,309	53,090.0	30.6	18.7 heavy
8-9	H	8.5	4,341	36,898.0	21.3	15.3

This is an index based on the percent in column C. The 25.0% of women age 35-44 who are heavy users is 7% lower than the 26.7% of total women who are heavy users. This yields an index of 93 (25.0% ÷ 26.7%).

The percent of all women age 35-44 who are heavy users of toothpaste. These percents project to each individual demographic break.

The percent of all heavy users who are age 35-44. Percents in this column add to 100% vertically.

The projected number of people in thousands. This reflects 3,117,000 women age 35-44 who are heavy users of toothpaste.

These illustrative data were taken from a 1982 SMRB Marketing Report. The headings reflect adult female users of toothpaste grouped by total, heavy, medium and light users.

Users of individual brands are reported in the same manner as heavy, medium and light users of the product category.

Figure 20. A Page From a Typical 1982 SMRB Marketing Report

Source: SMRB 1982.

females over 18 (Column C). To enumerate all users of toothpaste, one would consult the corresponding table for adults. That total would indicate the number of persons over 18 using toothpaste. The investigator must use judgment on a case-by-case basis to decide whether "adults" accurately represent the user population. In the case of toothpaste and similar hygiene products, census totals for persons between the ages of 1 and 17 should be added to the adult total derived from SMRB.

Examination of Tables 23 and 24 indicates the ease by which users of different brands or types of products can be enumerated. In most cases, the totals under Column A or the percentages in Column C are directly applicable to enumeration. Distinctions among adult users of different ages are easily made, if such distinction is required. Subsection 5.4.1 further discusses age and sex characterization of consumers using these data.

The SMRB data are clearly intended to describe the market variability of existing products. Consequently, the data are generally more applicable to existing chemicals and product formulations currently on the market than to new chemical substances. The SMRB data may, however, prove useful to assessments of PMN substances when the new chemical is intended for use as a substitute for an existing chemical. If use information included in a PMN submittal is sufficiently detailed, the SMRB data can be used to predict the number of exposed consumers. Method 5-2 summarizes the use of SMRB data for any chemical or product. Examples of the use of SMRB data are presented in Appendix A-4. That discussion provides clear methods for estimating the number of product users or the actively exposed population. Those who may be exposed to chemical residuals by their proximity to consumer products are passively exposed and are more difficult to enumerate accurately. Simmons' demographic data for households can be used toward this end, as illustrated in Method 5-2 and Appendix A-4.

The data set used to enumerate a product's users (by usage, type, or brand) also presents the frequency distribution of household size. For example, Table 22 indicates that 36,879,000 women use rug cleaners (Column A, all users, total female homemakers). Near the bottom of the page, still under Column A, are the numbers of households having 1, 2, 3 or 4, or 5 or more persons; these households also total approximately 36,879,000. To approximate the number of persons living in the 36,879,000 households, apply the frequency distribution and household size. Ranges can be used to accurately estimate the exposed population; use of the high end of the ranges generates a conservative estimate of exposed persons.

Method 5-2. Enumeration of Exposed Consumer Populations via the Use of Simmons Market Research Bureau Reports

Step 1 From the list of consumer products known to or thought to contain a chemical substance under investigation, identify those for which SMRB collects use data (Table 20). If SMRB does collect data, identify the appropriate product category volume(s) from Table 19.

Step 2 Identify applicable tables for enumeration as follows;

- If chemical substance is found in all types of products and brand names, the usage tables should be used.
- If chemical substance is found in only certain product types (e.g., aerosols versus liquids), the type tables should be used.
- If chemical substance is found in only certain brand names, the table on individual brand products should be used.

Step 3 Enumerate the actively exposed population as follows;

- If the exposed population is all adults and the data are available as such in SMRB, the column for all users (Column A) should be used. If the data are only available as adult males and adult females, the data in column A in each table should be added for the total exposed population. The investigator should decide whether children of less than 18 years of age are also actively exposed. If so, the age bracket should be determined and the total population in the U.S. for the age bracket should be obtained from Table 12 (Section 2.4). The adult percentage of users (Column C) should then be applied to the total number of children in the specified age bracket. The resulting population estimate should then be added to the total adult population for complete population enumeration.
- If only one member of the household is actively exposed, then the data for all users as listed for the product buyers (e.g., female homemakers) should be used to enumerate the exposed population.
- If the entire household is actively exposed but the SMRB data are only available for the type of buyer, the procedures to enumerate the exposed population are the same as the procedures to enumerate the passively exposed population described in Step 5.

Method 5-2. (continued)

Step 4 To enumerate the exposed population according to heavy, medium, or light exposure, the same procedures previously discussed are applicable; however, rather than using the column of data for all users, the columns of data for heavy, medium, and light users should be used. This should be done only when exposure levels are derived from the SMRB use patterns.

Step 5 To enumerate the passively exposed population, two approaches are possible. The second approach will provide a more accurate estimate. Both approaches assume that the actively exposed population will also be passively exposed.

Option 1 - Enumerate the actively exposed population as described in Step 3. Multiply this population by 2.73, which is the average number of members per household in the U.S.

Option 2 - Using SMRB collected demographics on the buyer's household size, multiply the household size by the number of buyers and then add the results to estimate the total passively exposed population. For example, to generate a conservative estimate:

1 person household = Number Buyers x 1 = A
2 person household = Number Buyers x 2 = B
3 or 4 person household = Number Buyers x 4 = C
5 or more person household = Number Buyers x 6 = D

A + B + C + D = total passively exposed population

5.3.2 Enumeration of Exposed Populations via Production and Sales Data

Users of consumer products can be enumerated by applying a number of assumptions and estimation techniques to economic data such as chemical production volume, Census of Manufactures output, and retail sales information. To enumerate the users of a consumer product, the investigator must estimate the number of units of a product bought by consumers, then apply data on usage patterns to determine the average number of consumers. The result of this calculation will be an estimate, but a fairly valid one; the components of the calculation are reliably predicted. An example of the method (Method 5-3) is presented in Appendix A-4.

The parameters specific to this calculation are the number of units of the product manufactured or sold annually and the annual usage patterns. The first, the number of units, can be derived in the manner described in problem 2 in Appendix A-4 (by assuming an average mass per unit) or by consulting published data. The Census of Manufactures (Bureau of the Census 1980) lists production of very specific products (by seven digit SIC code) in units such as pounds, kilograms, cases, etc. The assessor must assume that production equals sales to consumers. Other data bases containing this type of information and specific information on retail sales are listed in the consumer exposure assessment methods report (Volume 7). Use patterns can be either estimated on a product-specific basis or derived from the use information provided by SMRB data, as detailed in the previous Subsection (5.3.1).

It should be noted that this method of population estimation assumes that users are brand-loyal; i.e., for any product, a consumer either always or never uses a brand with the chemical. The result of this assumption is that some consumer populations may be underestimated; some individual exposures may likewise be overestimated. The calculated individual exposure resulting from the use of the product will be higher than if the consumer used various brands or formulations, some of which contained the chemical substance and some of which did not. The information needed to resolve this problem is not available at this time.

5.3.3 Enumeration of Exposed Populations via Chemical-Specific Information

Populations exposed to chemical substances in consumer products can be enumerated through the use of various sources of chemical-specific information. The approach is not as methodical as that applied to the use of market research data or economic (production and sales) data; rather, it entails researching information sources each time a chemical is assessed. The various types of information resources and the advantages and limitations of each are discussed below.

Method 5-3. Enumeration of Populations Exposed to Chemicals in Consumer Products Via the Use of Economic Data

Step 1 Determine the number of units of the product sold or produced annually.

Option 1 - consult the Census of Manufactures (Bureau of the Census 1980) to obtain production in unit quantities.

Option 2 - estimate the number of units produced by dividing the amount of the chemical destined for that use by the formulation percent and the total mass of product per unit.

Option 3 - consult Volume 7 for alternative sources of data (sales information, computerized data).

Step 2 Determine use patterns for the product. The SMRB presentation of heavy-medium-light use, discussed in Section 5.3.1, provides data for most products. Heavy use may, for example, be defined as 5 or more cans per week; medium use, 3 or 4 cans, and light use, 2 or fewer cans per week.

Step 3 Calculate the exposed population by dividing the production volume in units (from Step 1) by the units used per person per year (from Step 2).

(1) Direct contact with associations. Associations are able to provide many types of consumer-related information. Many associations are headquartered in the Washington, D.C., area and can be found in the telephone directory. The most comprehensive list of associations, however, is in the Encyclopedia of Associations (Gale Research 1980). Although associations can often provide the most accurate and precise estimates of consumer populations, acquiring the data may be time consuming and may therefore limit the usefulness of this method to detailed assessments.

When an association is consulted for population estimates, the contact should be informed of the reason for the request so that he can provide the best possible data. The representativeness of the data should be questioned; for example, a hobbyist association may be able to provide a membership number and also be able to say that the membership represents 75 percent of the total hobbyists.

Although there are some limitations to this approach, it has been used successfully in exposure assessments for many existing chemicals. When sufficient time and use information is available, PMN substances can be investigated in the same manner. Care must be taken to avoid disclosure of confidential business information (CBI) provided by PMN submitters.

(2) Government agencies. The Environmental Protection Agency (EPA), the Consumer Product Safety Commission (CPSC), and the Bureau of the Census can provide pertinent consumer information. The information is available through direct contact with experts in the agencies and the reports they publish.

CPSC has collected a great deal of information on recognized hazards such as asbestos. Information provided by CPSC may aid exposure assessments of consumer products containing existing chemicals and new substances intended as substitutes for recognized hazards. The CPSC, however, limits its data collection efforts largely to substances that have proved harmful. Unless a new chemical is similar in properties and is analogous in use to an existing chemical, CPSC's data are of little aid in investigating new chemicals.

The many publications of the Bureau of the Census may contain useful information. For example, those exposed to formaldehyde by residing in mobile homes were quantified (Versar 1982) by consulting the Annual Housing Survey (Bureau of the Census 1981). The Statistical Abstract of the United States (Bureau of the Census 1982) may also provide activity-related data that are useful in enumerating consumer populations.

Studies of existing chemicals are often conducted by more than one EPA Office and by many contractors. An exposure assessment of such a substance will benefit from a review of the published literature (available through the National Technical Information Service). The authors or sponsors of these reports may provide additional data if contacted directly.

Some consumer products are so widely used that one can safely assume the entire population of the U.S. may be exposed. For instance, all persons contact plastics and fabrics; common additives to them may cause nationwide exposure. The most recent data available from the Bureau of the Census should be used to enumerate the exposed population. Currently, a total of 226.5 million persons are reported to reside in the U.S. (Bureau of the Census 1982).

5.3.4 Enumeration of Consumers Performing Amateur or Hobbyist Activities

Consumers may be exposed to chemical substances in products designed mainly for use by professionals. Persons who do their own automobile maintenance and repair, house painting, lawn care, carpentry and remodeling, or photographic film development may be exposed to a chemical substance in a product that might be overlooked in a consumer exposure assessment. Enumeration of the exposed population may be keyed to the number of people engaged in these activities when other enumeration procedures, as previously discussed, are not possible. This method of enumeration, however, overestimates the exposed population because it assumes that all people who engage in a particular activity use the product or products containing the chemical substance.

All of the estimates assume that there is one amateur per household. The estimates presented below and summarized in Table 25 rely on the Bureau of Census (1982) estimate of 77,330,000 households in the U.S. and the following additional data.

(1) Automobile work. The U.S. Department of Energy (1980) estimates that 85 percent (65,700,000) of all households have at least one motor vehicle and that 55 percent of those households change their own oil. Thus, 36,100,000 households are estimated to have at least one person who changes his own oil.

(2) Painting. SMRB (1978) reports that 17.5 percent of U.S. households purchased exterior paint and 25.7 percent purchased interior paint during a one-year period. If it is assumed that the persons purchasing paint intended to use it themselves (rather than providing it to a hired professional painter), the potentially exposed population can be estimated. If only one member of each household uses paint, then 13,533,000 persons are actively exposed to exterior paint and 19,874,000 are exposed to interior paint. The members of each household would experience passive exposure to paint components, probably only in

interior paint. With an average of 2.78 persons per household, the passively exposed population is 55,250,000 persons.

(3) Lawn and garden care. The number of people who mow their own lawn provides a fair estimate of people who use fertilizers, pesticides, and other lawn and garden products. SMRB (1978) estimates that 37 percent of households own a lawn mower. Assuming that one person from each household is responsible for lawn care, an estimate of 28,612,000 people tend their own lawns.

(4) Carpentry. A rough estimate of the number of people who engage in carpentry can be made based on ownership of electric saws. Anyone seriously involved in carpentry and, therefore, potentially exposed to chemical substances in carpentry related products, would own this tool. SMRB (1978) estimates that 23 percent of all households own an electric saw. Therefore, at least 17,786,000 households include amateur carpenters.

(5) Remodeling. The number of people potentially exposed to chemical substances as a result of household remodeling activities can also be estimated from SMRB data. SMRB (1978) estimates that 1,132,000 basements, 2,313,000 kitchens, 2,572,000 bathrooms, and 3,898,000 other rooms were remodeled in 1976-77 by a household member. Based on the number of households in 1977 as estimated by SMRB, 74,019,000, the following percentages are derived; 1.5 percent of households had basements remodeled, 3.1 percent of households had kitchens remodeled, 3.5 percent of households had bathrooms remodeled, and 5.3 percent of households had other rooms (e.g., living rooms, bedrooms) remodeled by a household member. Assuming these data are representative of current remodeling activities, the percentages can be applied to the current number of U.S. households to calculate populations. The results are presented in Table 25.

(6) Photography. An estimated two to three million people develop their own film (Wolfram Report 1979). This would be 2.6 to 3.9 percent of the U.S. households, assuming that there is only one photographer per household.

5.4 Characterization of Exposed Populations

Exposed populations are often characterized by age and sex, since physiological parameters affecting exposure or risk are often age- or sex-dependent. Characterization of consumer populations is especially important, since many products are designed for or used by specific subpopulations.

Table 25. Summary of the Number of Households That Can Be Considered To Have at Least One Amateur or Hobbyist with Respect to a Specific Activity.

Activity	Number of households[1]	Percent of all households
Crankcase oil and filter change	36,100,000	47
Lawn and garden maintenance	28,612,000	37
Painting (exterior of house)	13,533,000	17.5
Painting (interior of house)	19,874,000	25.7
Carpentry	17,786,000	23
Remodeling		
Basement	1,160,000	1.5
Kitchen	2,397,000	3.1
Bathroom	2,707,000	3.5
Other	4,098,000	5.3
Photography	2,500,000	3

[1] Based on 77,330,000 households in the U.S. (Bureau of the Census 1982).

As was discussed in Subsection 5.3.1, the SMRB data are presented by detailed demographic characteristics. The populations reported as buyers/users of each product, assumed to be the actively exposed populations, are defined by sex and then stratified by age (see Tables 22 to 24). The characteristics of adults actively exposed to consumer products are therefore readily available. Less easily characterized are persons under the age of 18 and passively exposed populations. The SMRB data report only the relative frequency of the presence of children in the age groups of 0 to 2, 2 to 5, 6 to 11, and 12 to 17 years of age in the households with active users.

The only data available for characterizing the consumer population under 18 by age and sex are the national distributions presented in Section 2.4 of this volume (Table 12). Should such a characterization of the population be necessary, the assessor must assume that the affected group can be described by those data or a discrete subset thereof (i.e., males or females or some defined age group).

As described in Subsection 5.3.1, persons passively exposed in a user's household can be enumerated by use of the relative frequency of household sizes. However, no characteristics of the household members are available; generic data must be used to characterize that population. If it is assumed that the total population of persons living in households with users of the product represent a cross-section of the total U.S. population, the data (Table 12) in Section 2.4 of this volume can be used to describe the age and sex characteristics of the group.

Method 5-4 summarizes the steps to be performed in the characterization of populations exposed to chemical substances in consumer products.

Method 5-4. Characterization of Populations Exposed to Chemical Substances in Consumer Products

Step 1 If the consumer population was enumerated by the use of SMRB data, use the demographic characteristics reported for buyers/users to characterize the actively exposed population by age and sex.

Populations enumerated by other methods can also be characterized by consulting the SMRB report for the product(s) most similar to that being assessed.

Step 2 Consult Section 2.4 (Table 12) of this volume to derive generic age and sex characterization for:

- Consumer populations under the age of 18
- Passively exposed household members
- The entire population of the U.S.

6. POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES VIA THE INGESTION OF DRINKING WATER

6.1 Introduction

This section presents methods for the enumeration and characterization of populations exposed to chemical substances via the ingestion of drinking water. The methods described are applicable to publicly and privately supplied drinking water that may contain chemical substances as a result of (1) industrial, commercial, and household effluents to surface and ground water, (2) runoff or seepage from waste disposal sites, (3) non-point source runoff or seepage from agricultural and nonagricultural land uses, (4) drinking water treatment processes, (5) drinking water distribution systems, and (6) pollution of unknown origin. The methods are based on exposure as a result of the voluntary ingestion of drinking water; as such, the methods do not consider involuntary ingestion (e.g., swallowing of water during swimming) or dermal and inhalation exposure to chemical substances in drinking water.

Figure 21 is a flow diagram of the three-stage method framework for enumerating and characterizing populations exposed to chemical substances via the ingestion of drinking water. The following paragraphs briefly describe each of the stages; detailed information is provided in subsequent sections.

The first stage, identification of exposed populations, is accomplished by examining the sources of the chemical substance. Detailed information on procedures to complete a drinking water exposure assessment, which include identification of the exposed population, is included in Volume 5 of this series, in "Methods for Assessing Exposure to Chemical Substances in Drinking Water." Subsection 6.2, therefore, only briefly describes the procedures for identifying the exposed population.

Enumeration of the exposed population is discussed in Subsection 6.3. This stage involves the use of various computerized data bases that contain information on drinking water such as the sources of the raw water supply, intake locations, treatment methods, and populations served. Enumeration also involves the use of generic data on populations served when detailed geographic resolution is not required or when the financial or manpower constraints of the exposure assessment effort do not permit the development of detailed information.

The final subsection (6.4) describes the procedures for characterizing the enumerated population according to age and sex. Data sources are presented which will provide age and sex characteristics of

populations where geographic detail is required or generic age and sex characteristics for situations where specific detail is not required.

Examples of the use of the methods in this section are presented in Appendix A-5 of this report.

6.2 Identification of Exposed Populations

Exposed populations can be identified either through knowledge of the sources of chemical contamination or by examination of monitoring data. The former is a "materials balance" approach and comprises three types of sources:

1. Sources that can be geographically defined (e.g., industrial effluents and non-point sources of water pollution).
2. Sources related to the treatment processes used in production of potable water (e.g., use of chemicals as coagulant aids).
3. Sources within the distribution system (e.g., dissolution of solvents from glued pipe joints).

Monitoring data may identify water sources with contamination of known or unknown origin.

Comprehensive identification must consider all three source types as well as available monitoring data. Identification may be keyed to the geographic location of the water supply, treatment methods, distribution system type, or any combination of the three. The procedure for identification is presented as Method 6-1.

It is readily apparent that only Step 1 of Method 6-1 provides positive identification of exposed populations; the materials balance approach outlined in Steps 2 and 3 identifies those that are potentially exposed. The drinking water exposure assessment methods report (Volume 5) presents detailed methods for identifying exposed populations.

The populations identified in this stage must subsequently be enumerated. The following subsection discusses the methods for enumerating populations defined by the three types of sources and identified through monitoring data.

6.3 Methods for the Enumeration of Exposed Populations

This section discusses the recommended procedures and data sources for enumerating populations exposed to chemical substances via the ingestion of drinking water. The section is divided into four subsections based on the categories for identifying the exposed

Method 6-1. General Procedure for Identifying Populations Exposed to Chemical Substances in Drinking Water

Step 1 Obtain all available monitoring data for the substance being assessed. Monitoring data for finished water provides positive identification of an exposure source; however, it may not identify what the source is. The population served by the utility surveyed is an exposed population.

Step 2 Examine the environmental releases of the substance in the ambient environment. Knowledge of these releases, coupled with knowledge of the environmental fate of the substance in the aquatic environment, leads to identification of contaminated aquifers and surface waters. The persons drinking these waters are potentially exposed.

Step 3 Examine the uses of the substance. If it is used in the drinking water treatment or distribution systems, the populations served by those systems may be exposed.

(NOTE: Detailed information on identifying sources of chemical contamination and exposed populations is provided in Volume 5 of this exposure assessment methods report series.)

populations. Subsection 6.3.1 presents the procedures and data sources for enumerating exposed populations that are geographically defined by the sources of the chemical substance of interest; the procedures in Subsection 6.3.2 enumerate populations exposed to chemical substances as a result of drinking water treatment processes; the procedures in Subsection 6.3.3 enumerate populations exposed to chemical substances from the materials (e.g., pipes) used to distribute drinking water; and the procedures in Subsection 6.3.4 enumerate populations exposed to chemical substances that have been identified from water quality data collected during drinking water monitoring. The investigator's choice of an appropriate method should be based on how the exposed population has been identified.

6.3.1 Enumeration of Populations in Specific Geographic Areas

This section presents methods for enumerating populations in specific geographic areas where sources of the chemical substance of interest are located. These sources may include industrial, commercial, or household effluents, Publicly Owned Treatment Works (POTWs), waste disposal sites (e.g., landfills, wastewater lagoons), and transportation related spills. The individual volumes of this series discuss the data sources and procedures for identifying the sources of a chemical substance. Methods to link geographically-defined point sources with nearby drinking water intakes are discussed in the drinking water exposure assessment methods report (Volume 5). Identification of the sources of the chemical substance in turn permits the identification of the affected raw drinking water supplies. Identification of the raw water supplies, therefore, is the first step required. The type of raw water supply used, either surface water or ground water, determines the data bases that should be used in the population enumeration effort.

(1) Surface water. The principal data source for identifying both public and private drinking water utility companies that use surface water as their raw water supply is the Water Supply Data Base (WSDB). WSDB is a computerized data base maintained by the EPA Monitoring and Data Support Division, Water Quality Analysis Branch. It contains information on the location of surface water utilities; the locations of the utilities' treatment plants, intakes, and sources of raw water; the populations served; and the average and maximum daily production. A complete description of WSDB is available in Water Supply Data Base: Inventory of Surface Water Supplies and Addendum on a Groundwater Data Base Structure (Versar 1981).

The most useful application of WSDB is the integration of its data with data on sources and concentrations of chemical substances contained in other data files maintained by EPA-MDSD, such as the Industrial Facility Discharge (IFD) File and the STORET Water Quality Data Base. The data in each of these files can be accessed via another data base known as the REACH File. A complete description of the REACH File is not within the scope of this report; essentially, however, the REACH File is a data source for information on surface water, rivers, streams, lakes and reservoir segments that are coded within the U.S. Geological Survey's Hydrologic Unit Cataloging System. The drinking water intake locations in WSDB, the industrial discharge locations in IFD, and the locations of water quality monitoring stations in STORET are similarly coded with a REACH number. The REACH number, therefore, hydrologically links these files together. EPA-MDSD has developed several software packages to access the data contained in the various files via the use of the REACH number. Population data contained in WSDB may be obtained in this integrated approach. Method 6-2 lists the procedural steps of the integrated approach to obtaining information on sources, affected surface water supplies, and populations served. The drinking water exposure assessment methods report (Volume 5) provides a much more detailed description of WSDB and the other hydrologically linked data bases. (Note: Requests for data base retrieval should be directed to Mr. Phil Taylor, USEPA, Monitoring and Data Support Division, Water Quality Analysis Branch.)

The investigator will now have identified sources, raw water supplies, drinking water utilities, and populations served in one integrated process. EPA-MDSD is further expanding the usefulness of the integrated approach by assigning river mile indexes to all discharge points in IFD and intake points in WSDB. This will facilitate determination of the distances between these points. Distance calculations can then be used to model in-stream water quality dilution and the resultant concentration at drinking water supply intake points. Details on retrieval methods, keywords, and other integrated approaches are available in General Information on IFD, Drinking Water Supplies, Stream Gages, Reach, and Fishkill Files and Retrieval Procedures for Hydrologically Linked Data Files (USEPA 1981a).

The enumeration of populations exposed to chemical substances via surface water supplies contaminated by other sources (e.g., runoff from waste disposal sites, non-point sources) is also straightforward. The recommended approach is presented as Option 2 in Method 6-2.

The investigator should be aware of two limitations in WSDB, and they should be noted in the exposure assessment report. First, the intake location coordinates for drinking water utilities that serve populations less than 25,000 are only approximate locations (generally within ±10 minutes of latitude and longitude). Location coordinates for utilities serving more than 25,000 people are extremely accurate because they were developed from USGS 7.5-minute topographic maps. The second limitation is that the population data were collected between 1965 and 1975 and may not reflect current populations. If the data set of identified utilities is limited, the investigator should contact the drinking water utility supervisor and directly request up-to-date data on populations served by

Method 6-2. Enumeration of Populations Exposed to Chemical Substances in Surface Sources of Drinking Water Using the REACH File

Option #1 - To be used for surface sources contaminated by industrial and POTW effluents. For detailed information on the following steps, see Volume 5 of this methods series or USEPA (1981a).

Step 1 Identify applicable SIC codes for the chemical substance of interest (see Volume 2, Methods for Assessing Exposure to Chemical Substances in the Ambient Environment).

Step 2 Request retrieval of IFD data for facilities within SIC category (requests should be directed to Mr. Phil Taylor, USEPA, Monitoring and Data Support Division, Water Quality Analysis Branch, Washington, DC).

Step 3 Identify receiving water bodies by REACH number and USGS cataloging unit. (Note: The REACH number actually consists of 11 digits and includes the 8-digit USGS cataloging unit and the 3-digit EPA segment number. The segment number is frequently referred to as the REACH number. Retrievals limited to the entire 11-digit REACH number will identify water supply intakes and industrial discharges only on that particular segment. If a retrieval is made according to the USGS cataloging unit only, it will identify all points of interest in the USGS surface water drainage basin.)

Step 4 Request a hydrologic tree retrieval (HYDRO) from EPA-MDSD for each REACH number or cataloging unit identified. Include a request for populations served in the data tabulation. HYDRO will list in a tree diagram industrial discharge pipes, water supply monitoring stations, and water supply intake points according to hydrologic order. "Hydrologic ordering" provides stations on the most downstream reach first, and proceeds upstream, reach by reach.

Option #2 - To be used for surface sources contaminated by non-industrial effluents (e.g., chemical spills, non-point sources, waste disposal site runoff).

Step 1 Identify contaminated raw water supplies by USGS Hydrologic Units (8-digit number) using USGS State Hydrologic Unit Maps. Segment numbers, if desired, can be obtained from Mr. Robert Horn, EPA-MDSD, Monitoring Branch.

Step 2 Request WSDB retrievals from EPA-MDSD according to USGS hydrologic units. Include population served and intake name and location as parameters in data tabulation request. Check WSDB retrieval to determine whether listed utilities are withdrawing water directly from or downstream of the water body of concern.

the utilities' distribution system. (Note: Drinking water utilities will frequently perform a residential meter count rather than an actual head count of residential customers. If data are provided in this format, the investigator can assume 2.73 persons/meter based on Census data for the number of persons per household (Bureau of Census 1982a) to enumerate the total population.)

The WSDB is recommended as the primary data source for enumerating populations exposed to chemical substances via the ingestion of surface supplied drinking water. This is principally due to the inclusion of the REACH number in the data base structure. That number facilitates an integrated process of identifying sources (i.e., industrial and POTW dischargers) of chemical substances and enumerating exposed populations as previously described. There is another data base, however, that includes surface water populations served and intake locations. This data base, maintained by the EPA Office of Drinking Water, is known as the Federal Reporting Data System (FRDS). FRDS, discussed in the subsequent section on ground water, can be used as a source of information supplementary to that contained in WSDB. It can also be used to check the accuracy of the WSDB-listed population data. FRDS population data are updated annually by each primary agency (i.e., state or EPA region). As such, the population data is more accurate than the data stored in the WSDB. Cross-referencing of the two data bases is straightforward because WSDB listings include the FRDS utility number in the data structure. FRDS geographic restricted retrievals can be made by state, county (i.e., according to FIPS code), SMSA and USGS hydrologic units.* FRDS, however, does not include EPA developed stream segment numbers for intake locations; therefore, integrated data retrievals with other STORET and EPA-MDSD-maintained data files are not possible. The recommended method for obtaining and using FRDS data is presented in Method 6-3.

(2) Ground water. The principal data source for identifying either public or private drinking water utilities that use ground water is the previously mentioned Federal Reporting Data System (FRDS).

FRDS is an information management system used by both EPA headquarters and regional personnel to monitor program performance in each state. It contains inventory data as well as the compliance status of each public water supply. Separate data bases are maintained for each

---

*A.W. Marks, EPA-Office of Drinking Water, Washington, DC: personal communication with M. Callahan, EPA-Office of Toxic Substances; memorandum dated August 2, 1983.

Method 6-3. Enumeration of Populations Exposed to Chemical Substances in Surface Sources of Drinking Water Using the FRDS Data Base

Step 1 Request FRDS retrieval according to geographic area of interest (e.g., by state and/or county according to FIPS code, by SMSA according to SMSA code, or according to USGS cataloging unit).

Note: FRDS retrieval requests should be directed to:

Mr. Avrum Marks
Manager Computer Systems Staff
EPA Office of Drinking Water
Washington, DC 20460

Step 2 Scan retrieval for utilities listed that obtain raw water supplies from the water bodies of interest.

Step 3 Check for utilities that purchase finished drinking water from another utility. Under "source type," these utilities will be listed with the letter P. When totaling populations served, the investigator should not count population data for these utilities since these are already contained in the population served data for the utility that is processing the raw water. This avoids "double counting" the exposed population.

Step 4 Total the data on population served to enmumerate the total population exposed to the chemical substance of interest.

fiscal year after 1978 as well as the current year. FRDS became operational during January of 1979. As of April 15, 1980, information from all 57 states and territories, as well as information on Indian reservations within four EPA regions, had been received and processed.

Four types of data are collected by FRDS, based on regulatory reporting requirements (Marks 1980):

1. Inventory. This includes public water supply (PWS) capacity, source information, monitoring requirements, and facility name and address. Figure 22 is a sample report containing the types of information available for each PWS. However, since many of the data elements are not required for federal reporting, all of this information may not be available for each PWS.

2. Violation. This includes data pertaining to noncompliance with EPA or state standards by a specific water supply.

3. Variance and exemption. This includes data pertaining to authorized exceptions to the standards which are granted to a specific water supply.

4. Enforcement action. This includes information pertaining to actions taken against a public water supply.

In addition, summary statistics for each state are generated and maintained within the FRDS data base. The data types of greatest relevance are the inventory information and the summary statistics. Besides the ad hoc capabilities of the system, 11 standard reports have been generated. These are summarized in Table 26. The most useful are marked with an asterisk; they include reports listing data on populations served (number of meters), source location, treatment types (where available), and percentage breakdowns of data for individual states.

The procedure for enumerating populations exposed via ground water is to define the area of concern as determined by the sources of the chemical substance of interest (e.g., landfill leachate to ground water in a specific county or state). This step will be completed as part of the overall exposure assessment process. Detailed information on procedures for completing this step are presented in the drinking water exposure assessment methods report (Volume 5). The procedure is summarized in steps in Method 6-4.

The output of the procedure will be a list of all facilities in the geographic region selected (which may or may not be tapping the aquifer of interest), together with the population served and treatments used by each facility. The degree to which this information is complete depends on the thoroughness of the input from the particular state.

Figure 22. Example Printout of the Model State Information System-Public Water Supply Inventory for Redmond City, Oregon

Method 6-4. Enumeration of Populations Exposed to Chemical Substances in Ground Sources of Drinking Water

Step 1 Request a FRDS retrieval for the subject county and all surrounding counties: or by SMSA. This should be a "Comprehensive Listing" of all PWS using ground water in the subject counties or SMSA. Since the specific aquifer used as the source is almost never identified, it will have to be assumed that all local ground water facilities are potentially tapping the subject aquifer. The FRDS printout will supply data on populations served and treatment types used. When populations are totaled, the population data included in utility listings that purchase finished water (Code P under source type) should not be included. This avoids counting populations twice.

Step 2 FRDS does not include private wells. If necessary, this number can be deduced by conducting both surface water and ground water retrievals for the subject area, and subtracting population figures from the total population of the region (available from the Bureau of the Census (1982b)).

Table 26. Federal Reporting Data System (FRDS)
Description of 11 Standard Reports

Report Title	Description
*1. Public Water Systems - Comprehensive Listing	Lists all PWSs meeting the selection parameters, one per page, showing all PWS inventory data.
*2. Public Water Systems - Production and Capacity Data	Details production, capacities, meters, and services data for each PWS meeting the user's selection criteria.
*3. Public Water Systems - Service Area and Source Data	Lists service area location and characteristics and water source information, including treatments, for each PWS satisfying the user's selection criteria.
4. Public Water Systems - State Discretionary Data	Details all state discretionary data and variances and exemptions for each PWS satisfying the user's selection criteria.
*5. Number and Percentage of Facilities and Populations Served by Type of Water Supply Source	Shows this information by population category and by state.
6. Enforcement Actions Summary by Population	Shows number of enforcement actions occurring by state, population category, and type.
7. Enforcement Actions Summary by Type and Source	Shows number of enforcement actions occurring by state, type of action, and type of water source.
8. Violations Summary by Population	Shows number of violations occurring by state, population category, and type.
9. Violations Summary by Type and Source	Shows number of violations occurring by state, contaminant, type of violation, and type of water source.
10. Variances and Exemptions Summary by Population	Shows number of variances and exemptions by state, population category, and type.
11. Variances and Exemptions Summary by Type and Source	Shows number of variances and exemptions by state, contaminant, type, and type of water source.

* Indicates report useful for population enumeration effort.

Source: Marks 1980. As updated via personal communication by A.W. Marks, EPA-Office of Drinking Water, to M. Callahan, EPA-Office of Toxic Substances; memorandum dated August 2, 1983.

Although the WSDB is not, at this time, a useful data source for enumerating populations exposed via ground water, EPA-MDSD plans to expand the WSDB ground water coverage. The WSDB structure has been recently expanded to facilitate the storing of ground water utility information (Versar 1981). Included in the ground water utility information is the capability for recording the name and USGS-developed code for the aquifer from which the water is obtained. Presently, only the data for the 100 largest cities in the U.S., as identified by USGS in 1962 (Durfor and Becker 1964), have been added to WSDB. These data were updated in a telephone survey in 1981 (Versar 1981) before being added to the data base. The updating of WSDB with data on all ground water utilities in the U.S. is tentatively planned by EPA-MDSD pending determination of future funding priorities.

6.3.2 Enumeration of Populations Exposed via Treatment Methods

The screening of a chemical substance's sources may identify a drinking water treatment process, or lack thereof, that could result in human exposure. For example, the addition of a polyelectrolyte (e.g., polyacrylamide) to coagulate suspended sediments in raw water may add a residual contaminant (e.g., acrylamide monomer) to the finished drinking water. Similarly, the absence of activated carbon filtration treatment of raw water contaminated with organic chemicals may result in the production of finished drinking water containing organic chemicals. Exposed populations may, therefore, occasionally be identified by a treatment process or combination of processes. The primary data source for the enumeration of populations exposed via treatment processes is the FRDS Data Base discussed in Subsection 6.3.1(2).

FRDS contains figures for the number of people served for each listed public water supply system; in many cases treatment methods are also listed. Treatment information is not required by EPA but is often supplied by states. The population served by treatment type, therefore, is slightly inaccurate. It will, however, provide an estimate of the order of magnitude of the population size.*

The EPA Office of Drinking Water, which maintains FRDS, has put together several summary reports that relate populations, locations, and water source (ground vs. surface) with treatment processes (Marks 1980). These reports are listed in Table 26, Subsection 6.3.1(2). These reports are valuable as quick reference documents to enumerate populations when general geographic area information is required. For purposes of convenience, Table 27 summarizes the number of facilities and populations served by treatment processes for the entire U.S., based on 1980 data. When data for a specific geographic area are required, the investigator should request FRDS retrievals from the Computer Systems Staff, EPA Office of Drinking Water, as described in Method 6-5. Completion of these steps will result in the enumeration of the exposed population.

---

Table 27. Population Served by Drinking Water Treatment Processes for the U.S.

Treatment method	Number of facilities[1]	Population served (x 1,000)
Corrosion control	3,334	68,636
Softening	2,540	39,582
Taste and odor	2,941	97,728
Iron removal	4,275	54,773
Ammoniation	1,071	18,242
Fluoridation	7,150	115,392
Disinfection	20,663	171,666
Untreated	33,781[2]	20,530
Aeration	4,154	64,952
Prechlorination	4,791	76,952
Coagulation	4,615	117,309
Sedimentation	5,020	114,800
Filtration	6,265	117,066

Source: FRDS Data Retrieval FY 1980

[1] A facility is defined as a system serving >25 persons
[2] Primarily ground water systems

Method 6-5. Enumeration of Populations Exposed to Chemical Substances as a Result of Lack of Treatment Processes

Step 1 Identify the treatment process or processes of interest (e.g., coagulation, chlorination, fluoridation).

Step 2 Identify the source(s) of raw water (i.e., surface, ground, or both).

Step 3 Identify the geographic area of interest (e.g., state, county, SMSA, USGS cataloging unit).

Step 4 Request FRDS retrieval from EPA Office of Drinking Water according to the above-identified parameters. Include a listing of the population served in data retrieval request. Exclude utilities that purchase finished or raw drinking water ("P" code) to avoid counting populations twice.

NOTE: Reporting of treatment techniques is not required of states by EPA. The sizes of the populations covered by various treatment methods are generally under-reported. FRDS, therefore, provides only an order-of-magnitude estimate of the size of the exposed population.

6.3.3 Enumeration of Exposed Populations by Type of Distribution System

The distribution system may be a source of exposure to chemical substances. Distribution system components and potential contaminants are listed in Table 28.

It would be ideal to enumerate the populations served by each type of distribution system and component. This approach is not feasible for two major reasons:

- While it is simple to enumerate the customers served by any distribution system, it is nearly impossible to determine the components of any system. Many types of pipe are used in each system, and there is often no record of the type of piping.
- Neither historical nor current data on sales and use of pipe and other components in drinking water distribution systems are available.

Some qualitative generalizations about the relative uses of various pipes are possible. The generalizations are based on the applicability of different pipes in different situations.

Plastic pipe (usually polyvinyl chloride (PVC)) dominates the market in rural water systems. PVC pipe has long been accepted for drinking water supply, which is the main water use in rural areas. In urban areas, fire protection is a major concern, and the high pressures at which water is piped in cities do not allow the use of PVC. It has been estimated that 11.2 million rural Americans were drinking water from PVC pipes in 1979[*]. The number of urban users is unknown but is thought to be small. The relative proportion of Americans drinking water from PVC pipe is expected to increase, since PVC is used mainly in new construction areas.

In urban areas, the market for water pipe is very competitive. It appears to be fairly evenly split among concrete, ductile iron, asbestos-cement, and steel pipe in the 16-to 24-inch size range, and iron and copper for smaller pipe.[†] It should be noted that the smaller pipe (less than 16 inches in diameter) accounts for 90 percent of the linear footage of pipe laid.[‡]

[†] John Capita, American Water Works Assn., personal communication with Gina Hendrickson, Versar, Inc., April 1982.

[‡] Joe Willett, Concrete Pressure Pipe Assn., Personal communication with Gina Hendrickson, Versar, Inc., April 1982.

Table 28. Distribution System Components and Potential Contaminants

Component	Potential contaminant
Metal pipe (copper, iron, steel)	Metals; microbial products
Pipe joint glue	Organic solvents
Asbestos-cement pipe	Asbestos fibers
Lined pipe and plastic pipe	Plastic monomers, polycyclic aromatic hydrocarbons

A very rough estimate of the urban populations served by different types of pipe can be obtained from the preceding information. In reality, the population exposed via each type may range from less than 25 percent to 100 percent of the urban population, since no two types of pipe are incompatible and it is likely that more than one type is used in a single system.

6.3.4 Enumeration by Use of Monitoring Data

Monitoring data can be used to predict the number of persons drinking water containing a chemical substance. The method extrapolates data on the frequency of detection of the substance. The level of detail achieved by this tool depends on the form, representativeness, and sample size of the data. In its simplest form, the enumeration proceeds as shown in Method 6-6. The assumptions inherent in this very gross estimation include the assumption that the data are independent of the water source (surface or ground water). It must also be assumed that the data represent systems of all sizes, so that the frequency can be applied to the total population. Obviously, these assumptions limit the usefulness of the method; it should only be used in the absence of more refined data.

The investigator can improve this technique by breaking out the total population into groups defined by drinking water source or system size. Table 29 lists the populations served by systems of different sizes and source types. If the monitoring data indicate the source or system size, that information should be used since the following two considerations can greatly affect water quality:

- The fate of pollutants in surface and ground waters differ. While a chemical may volatilize from surface water, it may persist in an aquifer. Biodegradation may proceed at a slower rate in ground water because of lack of oxygen. More partitioning to soils and sediments may occur in groundwater because there is larger surface area available for absorption.

- Pollution (such as vehicle-generated heavy metal contamination) may be anthropocentric and consequently related to system size. Treatment techniques also vary by size of the system; generally, less sophisticated treatment is used in systems serving small populations.

If a pollutant's frequency of detection can be defined by either system size or source, the frequency can be applied to that subpopulation to derive an accurate estimate of the exposed population. Examples of this method are demonstrated in Appendix A-5.

The use of monitoring data to estimate the exposed population is limited in all cases by two assumptions. The sample size must be large

Method 6-6. Enumeration of Exposed Populations by the Use of Monitoring Data

Step 1 Calculate the frequency of detection from the monitoring data; if detected in 10 of 100 samples, the detection frequency is 10 percent.

Step 2 Multiply the detection frequency by the total population of the U.S. (226.5 million).

Table 29. Populations Served by Drinking Water System Size and Source Type[a]

System size	Surface water			Ground water			Surface and ground water		
	No. of systems	No. of persons	Percent of total[b]	No. of systems	No. of persons	Percent of total[b]	No. of systems	No. of persons	Percent of total[b]
25 - 100	1,649	83,000	0.04	22,716	1,145,000	0.54	24,365	1,228,000	0.58
101 - 500	2,644	541,000	0.26	16,554	4,016,000	1.9	19,198	4,557,000	2.16
501 - 1,000	1,378	989,000	0.47	4,969	3,566,000	1.7	6,347	4,555,000	2.17
1,001 - 2,500	1,890	3,157,000	1.5	4,434	7,406,000	3.5	6,324	10,563,000	5.0
2,501 - 5,000	1,257	4,575,000	2.2	1,965	3,038,000	1.4	3,222	7,613,000	3.5
5,001 - 10,000	899	6,265,000	3.0	1,349	9,401,000	4.4	2,248	15,666,000	7.4
10,001 - 100,000	1,550	38,567,000	18.2	2,572	37,107,000	17.5	4,122	75,674,000	35.7
100,000	233	70,303,000	33.2	72	21,725,000	10.3	305	92,028,000	43.5
TOTAL	11,500	124,480,000	58.7	54,631	87,404,000	41.3	66,131	211,884,000	100.0

[a] Does not include persons served by systems with fewer than 25 customers.

[b] May not total exactly because of rounding.

Source: Adapted from USEPA (1981b).

enough that the frequency of detection approximates the frequency of occurrence. The detection limit is the lower limit for estimating the exposed population via this method. Exposure below the detection limit may, however, be significant for certain chemicals.

6.4 Characterization of Exposed Populations

This subsection describes the data sources and procedures for characterizing the exposed population with respect to age and sex. In most exposure assessments, age and sex characterization will not be necessary. However, drinking water intake rates are a function of the individual's age and sex; characterization may be necessary to obtain a precise exposure distribution. If the chemical substance of interest has special effects on particular age classes such as children or the elderly, further characterization of the enumerated population is also indicated. If, for example, a chemical substance is determined to be teratogenic, enumeration of women of child-bearing age may be required.

The simplest and most rapid method of characterizing a large population is to assume that the age and sex distributions approach those of the total U.S. population. Table 12 of Section 2.4 of this report depicts the age and sex distributions by percent for the total U.S. population. These percentages should be applied to the population enumerated via the data sources discussed in the previous section in order to characterize the population exposed via drinking water.

Characterization within specific geographic areas, such as states, townships, and cities, is also straightforward and involves the use of census publications. General Population Characteristics, PC80-1-B Series (Bureau of the Census 1982b) provides the age and sex population data for most defined geographic areas. These data will frequently be provided as total population by age and sex and not as percentages in each age class or sex. The data, therefore, must be converted to a percentage basis. The calculated percentages are then applied to the population enumerated via one of the data sources discussed in the previous section.

APPENDIX A

APPLICATION OF METHODS TO EXAMPLE PROBLEMS

Page 170 missing

Introduction

The population enumeration methods report is a compilation of data, information resources, and methods. This appendix to the report is designed to illustrate some of the approaches recommended in the methods already discussed. A perusal of these examples will demonstrate that the methods are not necessarily steps that must be explicitly followed; the investigator must be flexible and creative when choosing among available methods and options.

This appendix is arranged as follows:

A-1: Populations Exposed to Chemical Substances in the Ambient Environment
A-2: Populations Exposed to Chemical Substances in the Occupational Environment
A-3: Populations Exposed to Chemical Substances via the Ingestion of Food
A-4: Populations Exposed to Chemical Substances via the Use of Consumer Products
A-5: Populations Exposed to Chemical Substances via the Ingestion of Drinking Water

In some cases the examples are hypothetical; other problems are based on actual problems encountered during the assessment of exposure to chemical substances.

The methods and data used in the compilation of this appendix are detailed in the text of the methods report. Whenever data limitations became apparent in the course of problem-solving, however, those limitations are discussed in the examples.

APPENDIX A-1

POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES IN THE AMBIENT ENVIRONMENT

Problem 1: Attached is a sample computer run of ATM-SECPOP. The model was used to estimate air concentrations of trichloroethane as a result of process emissions from a point source located in Texas. The purpose of the printout is to exemplify procedures used to perform ATM-SECPOP simulation.

 * Not yet implemented

Enter a model name: ATM

    The title of the run can be up to eighty characters long.  The
wording of the title is left to the user but typically should show
whether latitude and longitude, or zipcode, were used to identify
the emission site's location.

        Examples:

  **CHEMICAL XY, PLACE ANYWHERE, POPULATION BASED ON ZIPCODE -- 4/7/81**

Press RETURN to continue:
  **CHEMICAL PQ, PLACE SOMEWHERE, LAT/LONG USED -- 10/12/79**

Enter the title of this run: Site A, 1,1,1 - Trichloroethane

    The user should enter DEFAULT.  (In future versions of the system,
users will be able to supply alternatives to the default values).
Entering DEFAULT causes the following values to be used by ATM:

        Number of concentration points in each
         of the sixteen wind directions:           40
        Number of rings:                           10
        Ring distances (km):                       0.5, 1, 2, 3, 4,
                                                   5, 10, 15, 25, 50
        Number of concentration points per ring:   4

Enter the default status: DEFAULT

    The name of the point source can be up to twenty-four characters
long. This information must be supplied by the user at present.

Enter the name of the point source: Site A

    Type LAT/LONG or ZIPCODE to indicate the kind of source location
identifier you will use.  The source location identifier is LAT/LONG
if the user knows the geographic coordinates of the site, or ZIPCODE
if only the zipcode is known.  If both are available, the user should
use LAT/LONG.  Generally, more accurate results will be obtained if
the correct LAT/LONG is used.

Press RETURN to continue:
```

```
Enter the source location identifier: LAT/LONG

     The latitude is entered in degrees, minutes, and seconds.
Each of the components of the latitude should be separated from
the others by one space.

        Example:        N 34 32 10

This information must be supplied by the user at present.

Enter latitude in degrees, minutes, and seconds: N 28 59 10

     The longitude is entered in degrees, minutes, and seconds.
Each of the components of the longitude should be separated from
the others by one space.

Example:        W 76 54 32

This information must be supplied by the user at present.

Enter longitude in degrees, minutes, and seconds: W 95 24 45

     This model uses annual weather data for the selected locality.  The stations
within the indicated radius are located in the table below.  Choose the station
which best represents the source location's weather conditions.  If you are un-
sure which to choose, it is usually appropriate to select the closest one.  Type
the four digit station index number to indicate your choice.
     Weather stations within   75.0 km of the site:

Enter the four digit station index number: 0065

     The name of the emission type may be up to eight characters
long.  This name will be used to label the model output.  The
name you choose generally depends on the specific kind of pollu-
tant emission at the point source facility.  The emission type
name must be supplied by the user at present.

          Examples:        PROCESS
                           STORAGE

Enter the name of the emission type: PROCESS

     The source height defines the release height of the emission
in meters (m).  This information must be supplied by the user at
present.

Enter the PROCESS emissions source height in (m): 15.24

     The vent radius defines the radius in meters (m) of the point
source emission through a vent.  This information must be supplied
by the user at present.

Press RETURN to continue:
    The pollutant state identifier is GAS if the pollutant is
gaseous, or PARTICLE if the pollutant is a particulate.  This
information must be supplied by the user at present.

Enter the pollutant state: GAS

    The molecular weight of the gas must be supplied by the user
at present.

Enter the molecular weight: 133.4

    The atmospheric half life of the pollutant is entered in sec-
onds.  This information must be supplied by the user at present.
Please use the format shown in the examples, where 'E' precedes
the exponent in powers of ten.

        Examples:       1.557E8
                        1.020E9

Enter the half life in (s): 1.577E8

Control commands:

BACK            will return the user to the previous prompt.
CLEAR           will return the user to the Operation prompt.
EXIT            will return the user to VAX/VMS.
HELP            will display the appropriate HELP message.
GO              will begin processing of the user's fully
                 specified request.
AUTOHELP        will cause the HELP message to be displayed
Press RETURN to continue:
```

```
Enter the vent radius for PROCESS emissions in (m): .026

    The vent gas temperature defines the discharge temperature in
degrees Kelvin of the emissions through a vent.  This information
must be supplied by the user at present.

Enter the PROCESS vent gas temp in degrees (K): 311

    The ejection velocity defines the discharge ejection velocity
of the emissions in meters per second (m/s).  This information
must be supplied by the user at present.

Enter the ejection velocity for PROCESS emissions in (m/s): 1.524

    The emission rate defines the source strength of the emissions
in grams per second (g/s).  This information must be supplied by
the user at present.

Enter the PROCESS emission rate in (g/s): 2.755

    The name of the pollutant may be up to ten characters long.
It should be selected so that it identifies the chemical uniquely.

        Example:        PMN 81-XXX

This information must be supplied by the user at present.

Enter the name of the pollutant: 1,1,1-TCE

Press RETURN to continue:
```

```
                 for each prompt.
NOAUTOHELP      will cancel AUTOHELP.
RECAP           will display the session summary.
DATASET         will allow the user to change the current dataset.

Enter GO to begin processing: GO
```

NOTE: The following problem and solution is presented to demonstrate a possible approach for enumerating populations around point sources that are too numerous to deal with individually. Approaches, however, will have to be developed on a case-by-case basis for exposure assessments depending upon the availability of locational information and within the time and manpower constraints of the effort.

Problem 2: A chemical substance is known to be released from 100 point sources located in metropolitan areas throughout the United States. Using generic release characteristics, the following range of atmospheric concentrations has been estimated, via ATM, for radial rings within a 10 kilometer radius of the prototype source:

Radial Distance (km)	Concentration (ug/m^3)
0.0 - 0.5	1.4×10^0 - 7.0×10^0
0.5 - 1.0	2.0×10^{-1} - 1.2×10^0
1.0 - 2.0	4.6×10^{-2} - 2.4×10^{-1}
2.0 - 3.0	1.5×10^{-2} - 6.9×10^{-2}
3.0 - 4.0	7.3×10^{-3} - 3.3×10^{-2}
4.0 - 5.0	4.4×10^{-3} - 2.0×10^{-2}
5.0 - 10.0	1.9×10^{-3} - 8.7×10^{-3}

Estimate the population exposed at each concentration.

Solution: Since no other information on the location of the 100 sources is available, it is assumed they are located in metropolitan areas (SMSAs). To estimate the size of the population within each ring, the average population density of metropolitan areas in the U.S., 120 persons/km^2 (Table 8), was multiplied by the areas of each ring. Following are the results:

Radial Distance (km)	Prototype Ring Population
0.0 - 0.5	96
0.5 - 1.0	288
1.0 - 2.0	1136
2.0 - 3.0	1888
3.0 - 4.0	2624
4.0 - 5.0	3392
5.0 - 10.0	28,320

Since there are 100 sources nationwide and the prototype is assumed to be representative of all sources, the exposed population in each ring times 100 is equal to the total exposed population at each concentration range as follows:

Radial Distance (km)	Concentration Range (ug/m^3)	Exposed Population
0.0 - 0.5	1.4×10^0 - 7.0×10^0	9,600
0.5 - 1.0	2.0×10^{-1} - 1.2×10^0	28,800
1.0 - 2.0	4.6×10^{-2} - 2.4×10^{-1}	113,600
2.0 - 3.0	1.5×10^{-2} - 6.9×10^{-2}	188,800
3.0 - 4.0	7.3×10^{-3} - 3.3×10^{-2}	262,400
4.0 - 5.0	4.4×10^{-3} - 2.0×10^{-2}	339,200
5.0 - 10.0	1.9×10^{-3} - 8.7×10^{-3}	2,832,000

Problem 3: Area Source (Site Specific) - Chemical X is released as a result of vehicular emissions. Enumerate the population in the San Antonio SMSA that is exposed to different concentrations of chemical X given the following information: modeling of area source concentrations using meteorological factors characteristic of the San Antonio area determines that the atmospheric concentration of chemical X in urban areas is Y mg/m^3 and Z mg/m^3 in rural areas.

Solution: This problem was solved via application of Method 2-4 as follows:

The Bureau of Census publication, Number of Inhabitants (PC 80-1-A45), for 1980 provides the following data for the San Antonio SMSA. (Bureau of Census 1983a, Table 12, p. 52):

urban portion : population 985,149
rural portion: population 86,805

Therefore, populations are exposed to different concentrations of chemical X as follows:

y mg/m^3 = 985,149
z mg/m^3 = 86,805

Problem 4: Prototype Area Source - Chemical X is released as a result of the combustion of fossil fuels in home and industrial heating systems. The atmospheric concentration is directly related to population density and geographic location. Enumerate the population exposed to the different concentrations of chemical X according to the following modeling results;

	Concentration (mg/m^3)		
	Urbanized Area	Urban Area	Rural Area
Northeast	100	60	20
South	20	10	1
North Central	80	40	10
West	50	40	5

Solution: This problem was solved via application of Method 2-4 as follows:

Table 10 of the methods report provides 1980 population data for the U.S. based on census geographic regions. Data for the regions of interest are as follows:

	Population (x 10^3)		
	Urbanized	Other Urban	Rural
Northeast	35,520	3,484	10,232
South	39,639	10,743	24,967
North Central	32,822	8,644	17,388
West	31,130	5,083	6,953

These various population figures are readily matched up with the corresponding concentrations to yield the following results:

Concentration	Population (x 10^3)	
100	35,520	
80	32,822	
60	3,484	
50	31,130	
40	13,727	(8,644 + 5,083)
20	49,871	(39,639 + 10,232)
10	28,131	(10,743 + 17,388)
5	6,953	
1	24,967	

Problem 5: Line Source Example - Chemical X is imported to Baltimore, MD, and is distributed by railroad tank car to manufacturing sites in Richmond, VA; Pittsburgh, PA; Louisville, KY; and Newark, NJ. Leakage of chemical X along the transportation corridors results in an inhalation exposure to residents in the vicinity. Modeling of atmospheric concentrations based on the emission of X estimates the concentration to be z mg/m^3 within 0.5 mile of the rail lines. Enumerate the population exposed. Characterize the population by age and sex.

Solution: This problem was solved via application of Method 2-5 as follows:

Road atlases were consulted to determine distances between cities and the identity of central cities of SMSAs located on or very near straight lines drawn from Baltimore to each terminal city. Population density of each SMSA was calculated from 1980 data in the Bureau of Census publication, Number of Inhabitants (individual states). This reference provided total populations for each SMSA as well as the area (square miles) of each individual county. County areas were summed within an SMSA to determine total SMSA area. The number of people per square mile was then calculated. This information will be obtained much faster following publication of the U.S. Summary for Number of Inhabitants (mid 1983). The U.S. summary will list each SMSA along with population, land area, and population density.

Table 30 summarizes data and results for each route. Note that the Baltimore to Newark route presented problems that could not be solved by conventional use of the methodology. There are six SMSAs along the Baltimore-Newark corridor, including the end points. Each of these SMSAs borders directly on the next with no nonmetropolitan territory in between. Because of this, and because the subject SMSAs have odd shapes, the sum of all radii along the route calculated according to the previously discussed methods exceeds the actual distance between the terminal cities. Therefore, actual distances across SMSAs (straight lines through the central cities) were determined from road maps. The remaining three routes were analyzed by the conventional methods.

Table 30. Line Source Corridor Distances, Population Density, and Population Exposed in Problem 5

SMSA	Distance [a] (miles)	Density[b] (persons/mi^2)	Number of persons (x 10^3)
Baltimore to Newark (total distance 168 mi.)			
Baltimore	34	968	32.9
Wilmington	40	479	19.2
Philadelphia	46	1336	61.5
Trenton	11	1357	14.9
New Brunswick	15	1886	28.3
Newark	22	1954	43.0
Baltimore to Pittsburgh (total distance 218 mi.)			
Baltimore	27	968	26.1
Hagerstown	24	248	6.0
Pittsburgh	31	741	23.0
non-SMSA			
Baltimore to Hagerstown	25	38	1.0
Hagerstown to Pittsburgh	111	69	7.7
Baltimore to Louisville (total distance 598 mi.)			
Baltimore	27	968	26.1
Louisville	21	646	13.6
non-SMSA			
Baltimore to Louisville	550	38	20.9
Baltimore to Richmond (total distance 144 mi.)			
Baltimore	19[c]	968	18.4
Washington, D.C.	49	1090	53.4
Richmond	26	296	7.7
non-SMSA			
Washington, D.C to Richmond	50	38	1.9
TOTAL Population Exposed			405.6 x 10^3

[a] Distance in miles is equivalent to areas in square miles because width of corridor is 1 mile.

[b] Source: Number of Inhabitants.

[c] Adjusted to reflect fact that Baltimore and Washington, D.C., SMSAs are adjacent (compare treatment of Balitmore-Newark route in text).

Except for the Baltimore-Newark route, each SMSA is considered to be a circle. In Table 30, "distance" is equivalent to the radius of this circle in the case of a terminal SMSA, and equivalent to the diameter in the case of an intermediate SMSA. Radius or diameter was calculated from the area of the SMSA by the familiar formula, $A = \pi r^2$. Nonmetropolitan mileage was calculated as the difference between total length of route and the sum of all SMSA radii. The density of population in nonmetropolitan areas is taken for the appropriate region from Table 8 of the text.

The calculated total exposed population of 405.6×10^3 was characterized by age and sex. Proportions of each age and sex group were calculated from data in Table 12 of the text. Results are summarized in Table 31.

Table 31. Characterization of Exposed Population for Line Source Problem 5

Age Group	Male population (x 10^3)	Female population (x 10^3)
5	15.0	14.2
5 - 9	15.3	14.6
10 - 14	16.7	16.0
15 - 19	19.3	18.6
20 - 24	19.1	19.1
25 - 34	32.9	33.5
35 - 44	22.5	23.4
45 - 54	19.7	21.1
55 - 64	18.2	20.7
65 - 74	12.1	15.8
75 - 84	5.1	8.7
85+	1.2	2.8

(Numbers may not add to total due to rounding)

APPENDIX A-2

POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES IN THE OCCUPATIONAL ENVIRONMENT

Problem 1: Substance Y is a mineral contaminant of phosphate rock used in the preparation of fertilizers. How many persons are occupationally exposed to Y as a result of production, sales, and use of phosphate rocks and fertilizers?

Solution: This problem was solved via application of Method 3-1 and 3-2 as follows:

Step 1 - List of Establishments (from SIC manual)

- SIC 0711 - Soil Preparation Services (use)
- SIC 1475 - Phosphate Rock Mining (production)
- SIC 2874 - Phosphatic Fertilizers (production)
- SIC 5191 - Farm Supplies/Wholesale Distribution (Phosphate Rock - ground) (sales)
- SIC 5261 - Retail Nurseries, Lawn and Garden Supply Stores (fertilizers) (sales)

Step 2 - Determine Sources
(Economic Censuses)

Step 3 - Choose Data
(see Table 32)

Step 4 - Sum and qualification of data

1) 8,578
2) 5,900
3) 10,100
4) 35,772
5) 36,360

96,710 total exposed

1. SIC 0711 - is the only 4-digit code in the 071 class; populations reported for 071 and 0711 are equivalent. However, handling phosphatic fertilizers would only account for part of the activity described for this service industry.

Table 32. Employment by SIC Code for Producers and Users of Phosphate Fertilizers

SIC Found	Number of employees	Census cited
071	8,578 (paid employees)	1978 Agriculture
1475	5,900 (year average for production, development, and exploration workers for all types of operations)	1977 Mineral Industries
2874	10,100 (production workers)	1977 Manufactures
5191	35,772 (paid employees)	1977 Wholesale Trade
526	36,360 (paid employees)	1977 Retail Trade

2. SIC 1475 - the number reported would be representative of those actually exposed.

3. SIC 2874 - the number reported would again be representative of works actually exposed.

4. SIC 5191 - the number reported reflects a certain overestimation of those employees actually exposed to products containing contaminated phosphate rocks.

5. SIC 526 - similar to 0711, 5261 is the only 4-digit code in the 526 class; nonetheless, the reported number of paid employees is a gross overestimate of those actually exposed. (Exposure would be limited to accidental release of fertilizer from its packaging.)

Problem 2: Chemical Z is a reagent used in typing blood. (Typing is done in laboratories and is a common lab experiment in high school biology classes.) How many persons are exposed to chemical Z? Characterize that population by age and sex.

Solution: This problem was solved via application of Method 3-3 as follows:

Assumptions -(1) High school biology students are exposed in the classroom as is the teacher.

The exposed population will include:

- Medical/clinical technicians running tests.
- Biology teachers using this curriculum.
- Biology students of the appropriate grade.

Option 2 - Contact associations/appropriate representative organizations.

- National Association of Biology Teachers, Inc.
  Reston, Virginia 471-1134

Dr. Moyer: This test is done very infrequently because of resulting social problems it has posed with students and their families. Where it is done, this test is part of the 10th grade biology curriculum.

- National Science Teachers Association
  Washington, D.C. 328-5800

Dina Weiss: From the U.S. Registry of Junior and Senior High School Science and Math Teaching Personnel: most current estimate of biology teachers for grades 9 through 12 is 34,412 (at least 75% of national total).

- National Center of Educational Statistics
  (U.S. Department of Education), Washington, D.C. 436-7900

- Survey of national student enrollment for 1972 - 1973 school year in public schools, Biology I (10th grade) indicates 2,049,000 students.

- Statistics show that in 1972 the ratio of public to private high school students (grades 9-12) was about 10 to 1 (13,913,000/1,300,000).

- Statistics also show that since 1976, high school student enrollment in general has declined. 1982 survey results of public and private high school total enrollment shows about one million fewer students.

Option 3 - Occupation by Industry, 1970

- Health Technologists and Technicians employed at hospitals and with other health services.

Male	Female
16 to 24 = 12,911 + 2,050	16 to 24 = 42,824 + 12,379
25 to 44 = 25,545 + 7,169	25 to 44 = 55,150 + 23,195
45 to 64 = 7,917 + 4,720	45 to 64 = 22,616 + 8,937
65 + = 365 + 404	65 + = 1,413 + 694

Data Summation

(1) • 10th grade biology students best fit into the 15 to 19 year age category. From 1980 Census data (Table 12), the ratio of 15 to 19 year old men to women = $\frac{10,751,544}{10,410,123}$ = 1.03, or 0.508:0.492.

- In the 1972 - 1973 school year there were 2,049,000 Biology I students in public high school; and an estimated 204,900 Biology I students in private high school; totaling 2,253,900 Biology I students in 1972 - 1973. If general enrollment has decreased by about 10% since 1972, the current total would equal 2,028,510 high school students.

- Male: 16 to 24 = 1,030,483 Female: 16 to 24 = 998,027.

(ii)
- 34,412 currently registered high school biology teachers who could teach using the blood type test.

- Age and sex characterization for this special subpopulation is derived from the generic percentages of total employed in the "Professional, Technical, and Kindred" occupation classes (text Table 15):

Male	Female
16 to 24 = 7.2%	16 to 24 = 7.5%
25 to 44 = 33.5%	25 to 44 = 18.3%
45 to 64 = 16.9%	45 to 64 = 12.7%
65 + = 2.0%	65 + = 1.4%
~60%	~40%

The total percent ratio of male to female biology teachers (60 to 40) from the professional, technical, and kindred breakdown supplied by the 1970 occupational census (Table 15), agrees with the estimate of male to female biology teachers supplied by the National Science Teachers Association's registry.

(iii)
- Data for Health Technologist and Technicians employed in 1970 have been reported; the distribution is assumed to remain the same.

(iv)

Age Class	Male	Female
• 16 - 24	1,047,922	1,055,811
Students	(1,030,483)	(998,027)
Teachers	(2,478)	(2,581)
Technicians & technologists	(14,961)	(55,203)

• 25 - 44	44,242	84,642
Teachers	(11,528)	(6,297)
Technicians & technologists	(32,714)	(78,345)
• 45 - 64	18,453	35,923
Teachers	(5,816)	(4,370)
Technicians & technologists	(12,637)	(31,553)
• 65+	1,457	2,589
Teachers	(688)	(482)
Technicians & technologists	(769)	(2,107)
	1,112,074	1,178,965

- TOTAL = 2,291,339

Problem 3: Eight million lbs/yr of hexamethylenetetramine are produced at Chemical Synthesizers, Sioux Falls, South Dakota. They convert 1 million lbs/yr of that compound to another derivative for sale. How many persons are exposed to the derivative? How many production workers are involved? Characterize by age and sex.

Solution: This problem was solved via application of Methods 3-4 and 3-5 as follows:

Step 1 - **Option 2** - Direct enumeration using 1981 South Dakota State Industrial Directory (SIC 2899, Chemical Preparations).

Employment statistics
Office: male = 25 female = 25
Plant: male = 80 female = 46 (Total Plant = 126)

Step 2 - (From text, subsection 3.3.3)

$$\frac{PV_a}{PV_t} = \frac{E_a}{E_t}$$

$$\frac{1 \times 10^6 \text{lbs/yr}}{8 \times 10^6 \text{lbs/yr}} = \frac{E_a}{126 \text{ workers}}$$

$$16 = E_a \text{workers}$$

Using Method 3-5, characterize the population

Option 1 - (See Table 15 of text)

- Ages and sexes are derived from the generic percentages of total employed (16) in the "Operatives, Except Transport" occupation class:

Male	Female
16 - 24 (13.8%) = 2	16 - 24 (6.2%) = 1
25 - 44 (26.1%) = 4	25 - 44 (16.1%) = 2
45 - 64 (20.4%) = 3	45 - 64 (15.0%) = 2
65+ (1.4%) = 1	65+ (1.1%) = 0
10	6

Option 2 - State Industrial Directory indicates that there are 80 men and 46 women employed at the plant. The male:female ratio of 80:46, or 1.74 men for each woman, may be used to derive the population characterization by sex. Of the 16 employees exposed, 10 are men and 6 are women. The age distribution above still applies.

Problem 4: Chemical W, a volatile organic compound, is used in the formulation of specialty plastic products. Approximately 200 plants nationwide use chemical W. Because of its high volatility, production workers and non-production workers are exposed to chemical W vapor. OSHA inspection of 5 plants detected chemical W in all areas with the highest concentrations occurring in the production areas, particularly around melt pot and mold pouring points. Following are the site inspection data for the five plants:

Plant	1	2	3	4	5
Plant Consumption of W (lbs/yr)	100	10,000	50	1,500	500
Total number employees	15	70	9	40	125
Production employees	5	20	4	10	50
-Melters and Molders	2	6	2	6	4

Estimate the total number of (1) non-production employees, (2) production employees, and (3) melters and molders exposed to chemical W nationwide. What are the shortcomings in using the site inspection data?

__Solution__: This problem was solved via application of Method 3-4 as follows:

__Option 2__ - Extrapolation from sample data.

__Step 1__ - (Given)

__Step 2__ -
- Average number of non-production workers: 34
- Average number of production workers: 18
- Average number of melters and molders: 4

__Step 3__ - (x200 plants)

• Non-production workers	= 6,800	
• Production workers	= 3,600	
• Melters and Molders	= 800	
	11,200	National Total

Comments: Using actual field data that is relevant to the circumstances being assessed is of course the most defensible approach. However, it is difficult to qualify the representativeness of the sample group, i.e., are these plant data representative of all the plants in the field, and is this a large enough sample group?

APPENDIX A-3

POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES VIA THE INGESTION OF FOOD

Problem 1: Lettuce harvested for sale from the State of California has been treated with a chemical substance to reduce the susceptibility to attack by an insect indigenous to this geographic area. Enumerate the population in the United States that may be exposed to this chemical substance as a result of consuming lettuce harvested for sale from California.

Solution: This problem was solved by the application of Method 4-2 as follows:

Step 1 - Determine the percentage of users of lettuce. The best available source of information regarding the percentage of users of lettuce is the 1977-78 household food consumption survey (USDA 1982). This value is reported to be 69.7 percent of the households surveyed.

Step 2 - Calculate the consuming population or the upper range of the exposed population: Assuming that the household survey is representative of the consumption patterns of the total U.S. population, the percentage determined in Step 1 is multiplied by the total U.S. population in 1980 of 226.5 million.

$$.697 \times 226.5 \text{ million} = 157.9 \text{ million}$$

Step 3 - Determine the percentage of the U.S. total lettuce harvested from California. According to the 1974 Census of Agriculture (Bureau of the Census 1978), this value is 72.3 percent.

Step 4 - Calculate the lower limit of the exposed population. Multiply the percentage obtained in Step 3 by the value calculated for the consuming population from Step 2:

$$.723 \times 157.9 \text{ million} = 114.2 \text{ million}$$

The actual exposed population, therefore, is probably between 114.2 million and 157.9 million people.

Problem 2: Irish potatoes harvested for sale from Penobscot County, Maine, have been treated with a chemical substance to reduce their susceptibility to blight. Enumerate the population of the United States that may be exposed to this chemical substance as a result of consuming potatoes harvested for sale from Penobscot County, Maine.

Solution: This problem was also solved via the application of Method 4-2 as follows:

Step 1 - Determine the percentage of users of Irish potatoes. The best available sources of information regarding the percentage of users of Irish (white) potatoes is the 1977-78 household consumption survey (USDA 1982). This value is reported to be 72.8 percent of the households surveyed.

Step 2 - Calculate the consuming population or upper range of the exposed population. The percentage obtained in Step 1 is multiplied by the total U.S. population in 1980 of 226.5 million.

$$.728 \times 226.5 \text{ million} = 164.9 \text{ million}$$

Step 3 - Determine the percentage of the U.S. total represented by Irish potatoes harvested for sale from Penobscot County, Maine. According to the 1978 Census of Agriculture (Bureau of the Census 1982a), the quantity of Irish potatoes harvested for sale in the United States in 1978 (the most recent year for which data are available) is 314,929,746 hundredweight; the quantity harvested for sale in Penobscot County, Maine, is 1,122,414 hundredweight. The percent of the U.S. total of Irish potatoes harvested for sale in Penobscot County, Maine is:

$$\frac{1,122,414}{314,929,746} \times 100 = .36 \text{ percent}$$

Step 4 - Calculate the lower range of the exposed population. Multiply the percentage obtained in Step 3 by the value calculated for the consuming population from Step 2:

.0036 x 164.9 million = 593,600

The population exposed to the chemical substance, therefore, is between 593,600 people and 164.9 million people.

Problem 3: Yogurt produced in the United States is often packaged in plastic containers possibly containing a residual monomer that may leach from the packaging material into the food. Enumerate the U.S. population possibly exposed to this residual monomer as a result of consuming yogurt.

Solution: This problem was solved by the application of Method 4-3 as follows:

Step 1 - Determine the percentage of users of yogurt. The best available source of information regarding the percentage of users of yogurt is Food Consumption: Households in the United States, Spring 1977, (USDA 1982). This value is reported to be 12.5 percent of the households surveyed.

Step 2 - Calculate the consuming population. The percentage determined in Step 1 is multiplied by the total U.S. resident population in 1980 of 226.5 million:

.125 x 226.5 million = 28.3 million

The estimate of 28.3 million persons is the upper limit of the range of the potentially exposed population. To determine the lower limit of the exposed population, the percentage of yogurt packaged in plastic containers would have to be known. This information may be obtained by contacting the trade association that most closely represents packers of foods or dairy products.

Problem 4: A brand name beer is manufactured from spring water known to be contaminated with a chemical substance. Enumerate the U.S. population exposed to this chemical substance as a result of drinking this brand of beer.

Solution: This problem was solved via the application of Method 4-4 as follows:

Step 1 - Determine the number of users of the brand of beer. The number of users of this beer is reported by Simmons Market Research Bureau, Inc. (1977) to be 10,735,000 adults.

Step 2 - Calculate the exposed population. No adjustment is necessary if one assumes that only adults consume beer, since Simmons' data are representative of U.S. residents over the age of 18.

Problem 5: A certain brand of margarine is reported to be contaminated by a solvent used in cleaning process equipment. Enumerate the total population exposed to the solvent as a result of eating this brand of margarine.

Solution: This problem was also solved via the application of Method 4-4. It is based on the use of SMRB data which are currently not available. Data values are assumed according to the SMRB data format in order to demonstrate the method. SMRB data will be available to personnel of EPA-OTS and their contractors in the near future.

Step 1 - Determine the number of buyers. Simmons may report that 18,000,000 female homemakers buy this brand of margarine.

Step 2 - Calculate the exposed population. The sizes of the 18,000,000 households may be distributed as follows:

1 person household	2,000,000 x 1	2,000,000
2 person household	3,000,000 x 2	6,000,000
3-4 person household	8,000,000 x 4	32,000,000
5 or more person household	5,000,000 x 6	30,000,000
18,000,000 (total buyers)	70,000,000 (total consumers)	

Simmons' usage tables (as discussed in Section 5.0 of this report) present data on household size.

Problem 6: The Kanawha River in West Virginia has been contaminated by a chemical substance from an industrial effluent. Enumerate the population exposed as a result of consuming fish caught on a noncommercial basis.

Solution: This problem was solved via application of Method 4-5 as follows:

According to the 1975 West Virginia Fishing Survey, the number of fishermen fishing on the Kanawha River in 1975, the most recent year for which statistics are available, is 9,400. Assuming each fisherman catches and consumes fish, this number represents a lower limit for the actual exposed population. If one assumes that each fisherman represents a consuming household and that there are 2.78 persons per household (Bureau of the Census 1982b), then a rough approximation of the upper limit for the exposed population is 2.78 x 9,400 = 26,132.

Problem 7: A chemical substance is detected in five percent of the processed whole milk samples analyzed. Enumerate the population potentially exposed to the chemical substance.

Solution: This problem was solved via application of Method 4-8 as follows:

Step 1 - The monitoring data identify the contaminated food item as processed whole milk.

Step 2 - The total consuming population can be enumerated by the data presented in Food Consumption: Households in the United States, Spring 1977, (USDA 1982). According to the data for household use in a week, 65.5 percent of the household sampled bought fluid milk. The total consuming population is, therefore, .655 x 226.5 million = 148.4 million.

Step 3 - The frequency of detection is 0.05.

Step 4 - The lower limit of exposed population is
= 0.05 x 148.4 million
= 7.4 million

The population exposed to the chemical substance is between 7.4 million and 148.4 million people.

Problem 8: A contaminant in milk may result in significant risk to children between the ages of 0 and 8 years old. Estimate the exposed population for this age group.

Solution: This problem was solved via application of Method 4-2 and Method 4-9 as follows:

Step 1- According to USDA Household Consumption Survey of 1977-78 (USDA 1982), 65.5 percent of the households surveyed consume milk. The total milk consuming populations is approximated as:

0.655 x 226.5 million = 148.4 million

Step 2- According to the USDA Individual Food Consumption Survey of 1977-78 (USDA 1980) (see Figure 18 of text) 16.98 percent of the milk-consuming population is 8 years old or less. This was calculated by aggregating the consumers of milk for each age class less than 8 years of age and dividing by the total milk consuming population of the sample:

Number of consumers of fluid milk 8 years old or less
= (78 x 0.609) + (264 x 0.905) + (437 x 0.856) + (469 x 0.885)
= 1,076

Number of consumers of fluid milk = 9,620 x 0.659 = 6,340

Percentage of consumers who are 8 years old or less

$$= \frac{1{,}076}{6{,}340} \times 100 = 16.97 \text{ percent}$$

The estimated milk consuming population 8 years old or less is:

0.1697 x 148.4 million = 25.2 million

APPENDIX A-4

POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES VIA USE OF CONSUMER PRODUCTS

Problem 1: Chemical X is a solvent used in all aerosol rug cleaners currently marketed.

- How many persons are actively exposed?
- How many persons are exposed at heavy, medium, and light usage levels?
- How many persons are passively exposed?
- Characterize each population above by age and sex distribution.

Solution: This problem was solved via application of Method 5-2 using 1982 SMRB data and Method 5-4 as follows:

Step 1 - Rug cleaners.

Step 2 - SMRB Type tables used (aerosol).

Step 3 - Population actively exposed.

- Due to the inherent bias of the data base, we assume that only female homemakers are actively exposed (data for male counterparts are not available, though men do purchase and use rug cleaners to some extent).
- It is further assumed that use of this product is not restricted to any age group, i.e., that any female homemaker physically capable of applying the product does. Purchase = use = active exposure.

13,862,000 total female homemakers purchase aerosol rug cleaners, of which:

1,746,000 are 18 - 24 years of age, (12.6%);
3,855,000 are 25 - 34 years of age, (27.8%);
2,351,000 are 35 - 44 years of age, (17.0%);
2,232,000 are 45 - 54 years of age, (16.1%);
2,136,000 are 55 - 64 years of age, (15.4%); and
1,543,000 are 65+ years of age, (11.1%).

Step 4 - Since SMRB data are not provided for heavy, medium, and light (H, M, L) users of aerosol rug cleaners, the ratio of H:M:L users of all rug cleaner types is applied. This is derived from the appropriate SMRB data table for rug cleaners (1982 data).

(i) 36,879,000 total female homemakers use all types of rug cleaners of which:
13,063,000 are at heavy levels;
10,034,000 are at medium levels; and
13,783,000 are at light levels.

(ii) H:M:L =
0.35:0.27:0.37 = 1.00

(iii) Applied to the 13,862,000 total aerosol users:
4,852,000 are at heavy levels;
3,743,000 are at medium levels; and
5,129,000 are at light levels.

Step 5 - Population passively exposed.

Option 2

(i) Of the 13,862,000 total aerosol rug cleaner users:
1,566,000 live in single person households;
4,392,000 live in 2 person households;
5,878,000 live in 3-4 person households; and
2,026,000 live in 5 or more person households.

(ii) 1,566,000 x 1 = 1,566,000
4,392,000 x 2 = 8,784,000
5,878,000 x 4 = 23,512,000
2,026,000 x 6 = 12,156,000

Total passively
exposed population = 46,018,000
(men and women)

(iii) Method 5-4, using generic 1980 resident population characteristic data (text Table 12).
Ratio of males to females = 0.49:0.51,
applied to total population passively exposed = 22,548,820 males, of which:

1,711,455 are under 5 years of age (7.59%);
1,749,788 are 5 - 9 years of age (7.76%);
1,907,630 are 10 - 14 years of age (8.46%);
2,203,020 are 15 - 19 years of age (9.77%);
2,184,981 are 20 - 24 years of age (9.69%);
3,765,653 are 25 - 34 years of age (16.70%);
2,575,075 are 35 - 44 years of age (11.42%);
2,254,882 are 45 - 54 years of age (10.00%);
2,079,001 are 55 - 64 years of age (9.22%);
1,384,498 are 65 - 74 years of age (6.14%);
586,269 are 75 - 84 years of age (2.60%); and
139,803 are 85+ years of age (0.62%).

And 23,469,180 females, of which:

1,607,639 are under 5 years of age (6.85%);
1,642,843 are 5 - 9 years of age (7.00%);
1,797,739 are 10 - 14 years of age (7.66%);
2,098,145 are 15 - 19 years of age (8.94%);
2,147,430 are 20 - 24 years of age (9.15%);
3,766,803 are 25 - 34 years of age (16.05%);
2,633,242 are 35 - 44 years of age (11.22%);
2,375,081 are 45 - 54 years of age (10.12%);
2,328,143 are 55 - 64 years of age (9.92%);
1,776,617 are 65 - 74 years of age (7.57%);
978,665 are 75 - 84 years of age (4.17%); and
314,487 are 85+ years of age (1.34%).

Problem 2: A manufacturer submits a PMN for a new type of solvent to be used in rug cleaners. He plans to produce and market 500,000 kg/year.

- How many persons will be exposed, both actively and passively?

- Characterize the active and passive population by age and sex.

Solution: The solution of Problem 2 employs a variation of Method 5-3. The steps outlined below do not exactly match those presented in the method because the multitude of assumptions that must be made and the lack of available data. As was stated in the introduction to this Appendix, the method's primary function is to provide a framework for population enumeration and introduce the tools that can be used. The solution of this problem illustrates the creativity and flexibility that must be applied when utilizing the methods provided.

Actively Exposed Populations

- Gosselin's (1976) Clinical Toxicology of Commercial Products* was used to evaluate "solvents" as formulation components of these products. Because the term "solvent" can be ambiguous if not clearly described, it was assumed that the solvent subject of the PMN must (a) not be water; (b) be present in formulation in a significant proportion; and (c) be a volatile distillate used primarily as a support matrix that would evaporated very quickly immediately following application. Analysis of the information found in Gosselin et al. (1976) produced the following results:

Two types of "solvent" containing cleaners used predominantly for rugs and carpets were identified as:

(1) soap-solvent combination cleaners, that were
  - liquid
  - 15 - 45 (30%) solvent content
  - 45 - 95% water content
  - 0.7 - 5% ammonia content
  - 0 - 2% solids (soaps, borax, etc.)

---

*Gosselin RE, Hodge MC, Smith RP, Gleason MN. 1976. Chemical toxicology of commercial products. 4th edition. Baltimore, MD: The Williams and Wilkins Company.

(2) absorbent type cleaners, that were
- aerosol
- 25% solvent content, primarily light petroleum distillate
- 75% solids (as sorbants and propellant)

- Given: Solvent product = 500,000 kg/yr.
  Use: solvent in aerosol and liquid rug cleaners.

	Percent solvent (avg)	wt/unit cleaner (kg)[1]	$/kg[1]	#purchasers/yr[2]
Aerosol	25%	0.609	5.02	13,862,000
liquid	30%	1.340	3.82	18,939,000
powder	-	0.5435	6.33	6,044,000

---

[1] From Table 33

[2] From SMRB (text, Table 23)

36% of the purchasers purchase aerosols
49% purchase liquids
16% purchase powders

- There are two alternative assumptions which could be made to facilitate estimating the breakdown of the 500,000 kg between aerosol and liquid:

(1) Consumers use equal amounts by weight of each type. Therefore, 36% of the kg of rug cleaner produced is in aerosol form, 49% is liquid (and 16% is powder).

(2) Consumers use equal amounts by unit of each type. Therefore, 36% of the units produced are aerosol, 49% are liquid (and 16% are powder).

ASSUMPTION NO. 1: kg aerosol/person = kg liquid/person.

Step 1 - Determine how much of the 500,000 kg of chemical goes into aerosols and how much goes into liquids.

For every 36 kg of aerosol rug cleaner purchased, 49 kg of liquid are purchased. The aerosol contains 25% by weight of the chemical solvent in question, and the liquid contains 30%.

Table 33. Rug/Carpet Cleaning Products Market Survey Results[1]

Name		Reported weight[2] (kilograms)	Averaged retail price[3] (dollars)	Retail price per kilogram (dollars)
Aerosol Products:	(ounces)			
Scotchgard Carpet Cleaner		0.524	3.19	6.09
Woolite Rug Cleaner		0.624	3.19	5.11
Glamorene Spray'n Vac	(24)	0.680	2.89	4.25
Glory Rug Cleaner (Johnson Wax)	(24)	0.680	2.85	4.19
Lestoil Rug Cleaner (Noxell)	(19)	0.538	2.89	5.37
Carpet Magic Rug Shampoo	(19)	0.538	2.49	4.63
Bissell Foam Rug Cleaner	(24)	0.680	3.75	5.51
Average		0.609		5.02
Liquid Products:	(fluid ounces)

---

[1] Performed by Versar, November 1982.

[2] Conversion of fluid ounces to grams assumed density of water, using the formula:

$$\frac{1\ \text{gram}}{1\text{cc}} \times \frac{1000\ \text{cc}}{1\ \text{liter}} \times \frac{2.957\text{x}10^{-2}\ \text{liters}}{1\ \text{fluid oz.}} = \frac{29.57\ \text{g}}{1\ \text{fluid oz.}}$$

[3] Products appearing in several establishments with different prices display an average of those prices.

Thus:

% Total available solvent used in aerosol =

$$\frac{36\text{ kg aerosol} \times \frac{0.25\text{ kg solvent}}{\text{kg aerosol}}}{36\text{ kg aerosol} \times \frac{0.25\text{ kg solvent}}{\text{kg aerosol}} + 49\text{ kg liquid} \times \frac{0.30\text{ kg solvent}}{\text{kg liquid}}} \times 100\%$$

$$= 38\%$$

% Total available solvent used in liquid =

$$\frac{49\text{ kg liquid} \times \frac{0.30\text{ kg solvent}}{\text{kg liquid}}}{49\text{ kg liquid} \times \frac{0.30\text{ kg solvent}}{\text{kg liquid}} + 36\text{ kg aerosol} \times \frac{0.25\text{ kg solvent}}{\text{kg aerosol}}} \times 100\%$$

$$= 62\%$$

Thus,

190,000 kg solvent (500,000 x 38%) will be used in aerosols, and

310,000 kg solvent (500,000 x 62%) will be used in liquids.

Step 2 - Determine the kilograms of both aerosol and liquid products which could be produced from available solvent.

$$\text{kg aerosol product} = \frac{190{,}000\text{ kg}}{0.25} = 760{,}000\text{ kg } (42\%)$$

$$\text{kg liquid product} = \frac{310{,}000}{0.30}\text{ kg} = 1{,}033{,}333\text{ kg } (58\%)$$

This is what would be expected because if 36 kg of aerosol are purchased for every 49 kg of liquid, proportionally, 42% of the purchases would be aerosol and 58% would be liquid.

Step 3 - Determine number of persons actively exposed. Since products are purchased on a unit basis, the kg are converted to units:

$$\frac{760{,}000\text{ kg}}{0.609\text{ kg/unit}} = 1{,}248{,}000\text{ units of aerosol}$$

$$\frac{1{,}033{,}333}{1.34\ \text{kg/unit}}\ \text{kg} = 771{,}000\ \text{units of liquid}$$

If kg aerosol/person = kg liquid/person, then two aerosol units would be used per one liquid unit (2 x 0.609 kg/unit ~ 1.34 kg/unit). The following conclusions can be drawn:

	Possible consumption scenarios (per year) liquid	 aerosol	Number actively exposed
(Case 1)	1 unit	2 units	1,395,000 $\left(771{,}000 + \frac{1{,}248{,}000}{2}\right)$
(Case 2)	2 units	4 units	624,000 (1/2 x 1,248,000)
(Case 3)	3 units	6 units	465,000 $\left(\frac{771{,}000}{3} + \frac{1{,}248{,}000}{6}\right)$

ASSUMPTION NO. 2: Units of aerosol/person = units liquid/person

Step 1 - Determine how much of the 500,000 kg goes into aerosols and how much goes into liquids. 36 units of aerosol are produced for every 49 units of liquid. Thus:

% Total available solvent used in aerosol =

$$\frac{36\ \text{units aerosol} \times \frac{0.25\ \text{kg solvent}}{\text{kg aerosol}} \times \frac{0.609\ \text{kg aerosol}}{\text{unit aerosol}}}{36\ \text{units aerosol} \times \frac{0.25\ \text{kg solvent}}{\text{kg aerosol}} \times \frac{0.609\ \text{kg aerosol}}{\text{unit aerosol}} + \left(49\ \text{units liquid} \times \frac{0.30\ \text{kg solvent}}{\text{kg liquid}} \times \frac{1.34\ \text{kg liquid}}{\text{unit liquid}}\right)} \times 100\%$$

$$= 22\%$$

% Total available solvent used in liquid =

$$\frac{49\ \text{units liquid} \times \frac{0.30\ \text{kg solvent}}{\text{kg liquid}} \times \frac{1.34\ \text{kg liquid}}{\text{unit liquid}}}{49\ \text{units liquid} \times \frac{0.30\ \text{kg solvent}}{\text{kg liquid}} \times \frac{1.34\ \text{kg liquid}}{\text{unit liquid}} + 36\ \text{units aerosol} \times \frac{0.25\ \text{kg solvent}}{\text{kg aerosol}} \times \frac{0.609\ \text{kg aerosol}}{\text{unit aerosol}}} \times 100\%$$

$$= 78\%$$

Thus,

110,000 kg solvent (500,000 x 22%) will be used in aerosols, and

390,000 kg solvent (500,000 x 78%) will be used in liquids.

Step 2 - Determine the number of units which can be produced.

$$\text{units aerosol product} = \frac{110{,}000 \text{ kg}}{(25\%)(0.609 \text{ kg/unit})} = 722{,}000 \text{ units } (43\%)$$

$$\text{units liquid product} = \frac{390{,}000 \text{ kg}}{(30\%)(1.34 \text{ kg/unit})} = 970{,}000 \text{ units } (57\%)$$

As with Step 2 of assumption one, approximately 43% and 57% would be what was expected.

Step 3 - Determine the number of persons actively exposed.

If units of aerosol/person = units of liquid/person, then one aerosol unit would be used per one liquid unit. The following conclusions can be drawn:

	Possible consumption scenarios (per year) liquid	aerosol	Number actively exposed
(Case 1)	1	1	1,692,000 (722,000 + 970,000)
(Case 2)	2	2	846,000 (1/2 x 1,692,000)
(Case 3)	3	3	564,000 (1/3 x 1,692,000)

- Without more information on actual personal consumption patterns of these products, neither assumption one nor assumption two provide "more accurate" exposure numbers. So, for the purpose of the continuation of this analysis, a "worst case" value will be adopted to represent exposure for this problem (assumption two, case one = 1,692,000).

Passively Exposed Populations

The enumeration of the population passively exposed to the solvent-containing rug cleaning products is based on the actively exposed population and follows the methods outlined in Step 5 of Method 5-2, with some modification.

Assume that the same percentage of household sizes identified for all rug cleaner users applies to the population enumerated for rug cleaner users. (Actively exposed to the PMN solvent).

(i) From SMRB data; text Table 22.

Household of:	1 person	2 people	3-4 people	5+ people
Percentage:	12.6%	30.8%	40.1%	16.5%

(ii) 1 person household = 1,692,000 x 0.126 x 1 = 213,000
2 person household = 1,692,000 x 0.308 x 2 = 1,042,000
3-4 person household = 1,692,000 x 0.401 x 4 = 2,714,000
5 + person household = 1,692,000 x 0.165 x 6 = 1,675,000

Total passively exposed population = 5,644,000

Characterization of actively and passively exposed populations.

(i) The actively exposed population (100% female) is characterized for age distribution using the SMRB data base. (Text Table 22). These data indicate:

Years of age	Percent of total
18-24	10%
25-34	24%
35-44	19%
45-54	16%
55-64	15%
65+	15%

These percentages applied to the 1,692,000 females actively exposed results in the following:

169,200 are 18-24
406,080 are 25-34
321,480 are 35-44
270,720 are 45-54
253,800 are 55-64
253,800 are 65 or older

(11) Characterization of the passively exposed population (males and females) relies entirely on generic U.S. Census data (text Table 12). Ratio of males to females = 0.49:0.51. Applied to the total population passively exposed (5,644,000), 2,766,000 are male of which:

210,000 are under 5 years of age (7.59%);
215,000 are 5 - 9 years of age (7.76%);
234,000 are 10 - 14 years of age (8.46%);
270,000 are 15 - 19 years of age (9.77%);
268,000 are 20 - 24 years of age (9.69%);
462,000 are 25 - 34 years of age (16.70%);
316,000 are 35 - 44 years of age (11.42%);
277,000 are 45 - 54 years of age (10.00%);
255,000 are 55 - 64 years of age (9.22%);
170,000 are 65 - 74 years of age (6.14%);
71,900 are 75 - 84 years of age (2.60%); and
17,100 are 85+ years of age (0.62%).

And, 2,878,000 are female of which:

197,000 are under 5 years of age (6.85%);
201,000 are 5 - 9 years of age (7.00%);
220,000 are 10 - 14 years of age (7.66%);
257,000 are 15 - 19 years of age (8.94%);
285,000 are 20 - 24 years of age (9.15%);
462,000 are 25 - 34 years of age (16.05%);
323,000 are 35 - 44 years of age (11.22%);
291,000 are 45 - 54 years of age (10.12%);
285,000 are 55 - 64 years of age (9.92%);
218,000 are 65 - 74 years of age (7.57%);
120,000 are 75 - 84 years of age (4.17%); and
38,600 are 85+ years of age (1.34%).

APPENDIX A-5

POPULATIONS EXPOSED TO CHEMICAL SUBSTANCES VIA INGESTION OF DRINKING WATER

Problem 1: Point Source Surface Water - Chemical Q is discharged from a plant located in Lambertville, NJ (40°22'00" - 74°56'10") to the Delaware River. Surface water monitoring has detected Chemical Q downstream of the plant as far as Wilmington, DE. Enumerate the population potentially exposed to Chemical Q because their drinking water is obtained from the Delaware River. Chemical Q is teratogenic. How many women of child-bearing age are potentially exposed?

Solution: This problem was solved via application of Method 6-2 as follows:

Step 1 - Not applicable

Step 2 - Not applicable

Step 3 - The first step towards solution of this problem was the identification of the USGS cataloging units of concern between Lambertville, NJ and Wilmington, DE. Cataloging units were obtained from USGS Hydrologic Unit Maps for the states of New Jersey, Pennsylvania, and Delaware. The cataloging units are:

02-04-02-05
02-04-02-04
02-04-02-03
02-04-02-02
02-04-02-01
02-04-01-05

The next step was the identification of the downstream and upstream Delaware River REACH numbers between which drinking water intakes are to be identified. REACH numbers were obtained from REACH maps on file at the EPA-Monitoring and Data Support Division, Water Quality Analysis Branch. The cataloging unit and REACH (segment) numbers to which the eventual WSDB retrieval was limited are:

02-04-01-05-006 (Lambertville, NJ)
02-04-02-04-002 (Wilmington, DE)

Step 4 - A hydrologic tree retrieval was requested from the EPA-Monitoring and Data Support Division. The retrieval request was limited to drinking water utilities on the Delaware River mainstem as stored in WSDB between the above listed cataloging units. Figure 23 is the output received. Listed below are the utilities and the exposed population (i.e., population served);

```

Figure 23. "Hydro Tree" Retrieval for Delaware River Mainstem Between Lambertville, NJ, and Wilmington, DE.

Facility	Exposed Population
Philadelphia Water Dept.	1,950,098
Bristol Water Dept.	30,000
Lower Bucks Water Dept.	90,000
U.S. Steel Water Dept.	8,000
Morrisville Water Dept.	21,000
Lambertville Water Dept.	4,400
Trenton Water Dept.	250,000
Keystone Water Dept.	2,616
Total	2,356,114

"Child-bearing age" is taken as 15 to 44 years of age. The percentage of the U.S. population that is female and within that age group was calculated from Table 12 of the text. Results are as follows:

Age Group	Percent of Total U.S. Population
15-19	4.60
20-24	4.70
25-34	8.25
35-44	5.77
Total	23.32

2,356,114 x 0.2332 = 549,446

Therefore, 549,446 women of child-bearing age are potentially exposed to Chemical Q.

Problem 2: Point Source Ground Water - A waste disposal site on the outskirts of Miami, FL, leaches Chemical K to ground water. Monitoring data has detected K in ground water in all directions up to 50 miles from the site. Enumerate the population potentially exposed to K via drinking water from public and private ground water systems in this area.

Solution: The solution to this problem is based on a slight modification of Method 6-4.

Step 1 - The first step was the identification of the counties around Miami affected by the ground water contamination. This was accomplished by the use of a 1° x 2° topographic map of the Miami area. The 50-mile radius of the waste disposal site basically includes all of Dade County, Florida.

Step 2 - An FRDS retrieval restricted to drinking water utilities in Dade County was requested from the computer system staff of the EPA-Office of Drinking Water. The FRDS retrieval revealed a complex web of public, private, industrial, and business facilities which use ground water for drinking purposes. A total of 472 systems were listed with the major one being the Miami - Dade County Water and Sewer Authority which serves 500,000 people. A sample of an FRDS printout for this system is presented in Figure 24. Only one surface water utility serving 9,037 people, however, was listed. It was felt, therefore, that a more accurate enumeration of the exposed population would be obtained by obtaining the current population of Dade County. This avoids counting any populations twice and also includes those people who have private wells in their home. According to the Census publication, Number of Inhabitants (1980), the total population of Dade County, in which Miami is located, is 1,625,781. This is also the population potentially exposed to the chemical substance. That population which consumes surface supplied drinking water is insignificant; it is also highly probable that they consume ground supplied drinking water at the place of work or other business concerns.

Problem 3: Treatment Method Example - An industrial plant located in Cincinnati, OH, discharges a non-toxic substance to the Ohio River. This substance, however, reacts with flourine to produce a toxic chemical. The non-toxic substance has been detected in the Ohio River 100 miles downstream of the plant. Enumerate the population which consumes flouridated drinking water obtained from the Ohio River and is potentially exposed to the toxic chemical formed.

Solution: This problem was solved by using a combination of Method 6-2 (as in Problem 1) and a modification of the approach discussed in Section 6.3.2 of the text.

Step 1 - The cataloging units and REACH numbers of the inclusive section of the Ohio River 100 miles downstream of Cincinnati were identified from USGS hydrologic unit maps of Ohio and Kentucky and REACH maps on file at the EPA-Monitoring and Data Support Division. The upstream and downstream cataloging units and REACH numbers are as follows:

05-14-02-06-001 (100 miles downstream)
05-09-02-01-001 (Cincinnati)

Figure 24. Sample FRDS Retrieval for the Miami-Dade Water & Sewer Authority

Step 2- A hydrologic tree retrieval restricted to water supplies on the Ohio River between these river segments was requested from the EPA-Monitoring and Data Support Division, Water Quality Analysis Branch. The output is similar to Figure 23, previously presented. The purpose of this retrieval was twofold (1) to identify utilities and (2) to obtain the FRDS number of the utilities identified. The FRDS number would then be used to retrieve treatment information for those facilities from the FRDS Data Base of the EPA-office of Drinking Water. The retrieval, however, revealed that only three facilities withdraw drinking water from the Ohio River within 100 miles downstream of Cincinnati. These are the Newport Water Works, the Cincinnati Water Department, and the Kenton County Water Works. Since so few facilities are involved, it was decided to call each individually instead of conducting an additional retrieval. They were each contacted; each indicated that they do fluoridate their water. Therefore, the population exposed to the toxic reaction product is the total population served by the three facilities. This was calculated from the retrieval data as follows:

Newport Water Dept.	30,000
Cincinnati Water Dept.	850,000
Kenton Water Dept.	52,000
Total	930,000 persons potentially exposed .

Problem 4: Monitoring Example - Chemical S is ubiquitous. As a result of nationwide sampling of both finished surface and ground obtained drinking water at over 100 plants, the following detection frequency is observed.

Concentration	Cumulative detection frequency in finished surface water	Cumulative detection frequency in finished groundwater
≤10 ug/l	10%	1%
≤ 5 ug/l	50%	25%
≤ 1 ug/l	95%	50%

Enumerate the population exposed to chemical S at the three concentrations.

Solution: This problem was solved using a combination of the data in Table 29 and Method 6-6.

Step 1 - The first step was the calculation of the relative percent of use of surface and ground water in the U.S. This was accomplished as follows:

From Table 29:

Population consuming surface water = 124,480,000
Population consuming ground water = 87,404,000

It is assumed, since the data in Table 29 do not include systems of fewer than 25 people, that the difference between the current U.S. population (226,504,000) and the total of the above is the population which consumes water from private wells (14,620,000). This population is included in that population which consumes ground water. Therefore, the relative use of ground and surface water is as follows:

$$\text{Surface} = \frac{124{,}480{,}000}{226{,}504{,}000} = 0.55$$

$$\text{Ground} = \frac{87{,}404{,}000 + 14{,}620{,}000}{226{,}504{,}000} = 0.45$$

Therefore, the populations exposed to different concentrations of S are as follows:

Concentration	Detection frequency		Fraction of U.S. population[a]	Number of persons (x10^6)[b]
	Surface	Ground		
10	.1	.01	0.060	13.6
5	.5	.25	0.388	87.9
1	.95	.50	0.748	169.4

[a] (surface frequency x 0.55) + (ground frequency x 0.45)

[b] fraction x 226.5 million (1980 U.S. population)

Problem 5: Source Type. A pollutant is detected in five percent of surface water supplies and 50 percent of ground water supplies. Enumerate the potentially exposed population.

Solution: This problem was solved via application of Method 6-6 and the data in Table 29 of the text as follows:

Frequency of detection in surface water = 0.05
Population served by surface water = 124,480,000
Frequency of detection in ground water = 0.50
Population served by ground water = 87,404,000
Population exposed = (0.05)(124,480,000) +(0.50)(87,404,000)
= 49,926,000 persons

Problem 6: System size. A pollutant is detected in 20 percent of finished waters serving fewer than 10,000 persons, but in 70 percent of those serving over 10,000 persons. Enumerate the potentially exposed population.

Solution: This problem was also solved via application of Method 6-6 and the data in Table 29 as follows:

Frequency of detection in "small" systems = 0.20
Population served by "small" systems = 44,182,000
Frequency of detection in "large" systems = 0.70
Population served by "large" systems = 167,702,000
Population exposed = (0.20)(44,182,000) + (0.70)(167,702,000)
= 126,228,000 persons

APPENDIX B

EXAMPLES OF DATA BASES USED IN OCCUPATIONAL POPULATIONS METHODS SECTION

Appendix B. Examples of Data Bases Used in Occupational Population Methods Section

(1) 1970 Census of Population: Occupation by Industry

- Sample of Table 1. Industry group of employed persons by occupation, age, and sex: 1970.

(2) The National Industry - Occupation Employment Matrix, 1970, 1978, and Projected 1990. Volume I.

- Sample of Table 1. Percent distribution of industry employment by occupation, 1970, 1978, and projected 1990.

(3) The National Industry - Occupation Employment Matrix, 1970, 1978, and Projected 1990. Volume II.

- Sample of Table 2. Percent distribution of occupational employment by industry, 1970, 1978, and projected 1990.
- Sample of Table 3. National nonagricultural employment of wage and salary workers by industry, 1970 and projected 1990.
- Sample of Table 4. Total national employment by industry, 1970, 1978, and projected 1990.
- Sample of Table 5. National 1978 employment, projected 1990 requirements, and average annual openings, 1978-90, by occupation.

(4) Employment and Earnings. October 1981.

- Sample of Table B-2. Employees on nonagricultural payrolls by industry.

(5) Example of 1977 Economic Census Reports - 1977 Census of Manufactures: Industry Series. Industrial Organic Chemicals. SIC 2861, 2865, and 2869.

- Samples of tables containing employment information.

(6) Procedures used to Develop the 1978, 1979, 1980 and Projected 1990 OES Survey - Based Matrix

USERS' GUIDE IN LOCATING STATISTICS BY TABLE NUMBER

(For explanation of terms, see appendix A)

	Item	4-digit industry statistics		
		Historical	Operating ratios	By geographic area
1	Number of manufacturing establishments	1a		2
	Employment and payroll:			
2	Number of employees	1a	1b	2
3	Payroll	1a	1b	2
4	Supplemental labor costs			
5	Production workers	1a	1b	2
6	Production worker hours	1a	1b	2
7	Production worker wages	1a	1b	2
	Shipments, cost of materials, and value added:			
8	Value of shipments (4-digit)	1a	1b	2
9	Product class shipments (5-digit)			
10	Product shipments (7-digit)			
11	Value added by manufacture	1a	1b	2
12	Cost of materials	1a	1b	2
13	Cost of fuels and electric energy			
14	Materials consumed by kind			
	Inventories:			
15	End of year	1a		
16	Stage of fabrication			
	Capital expenditures, assets, rental payments, and purchased services:			
17	New capital expenditures	1a		2
18	Used plant and equipment expenditures			
19	Gross assets	1a	1b	
20	Depreciation			
21	Retirements of buildings and machinery			
22	Rental payments			
23	Purchased services			
	Ratios:			
24	Specialization	1a		
25	Coverage	1a

- Represents zero. (D) Withheld to avoid disclosing operations of individual companies. (NA) Not available. n.e.c. Not elsewhere classified. r Revised. (S) Withheld because estimate did not meet publication standards. (X) Not applicable. (Z) Less than 50 thousand dollars or hours; under 50 employees.

[1] In annual survey of manufactures (ASM) years, data are estimates based on a representative sample of establishments canvassed annually and may differ from results of a complete canvass of all establishments. ASM publication shows percentage standard errors. Unless otherwise noted, for data prior to 1963, see 1963 Census of Manufactures, vol. II, table 1 of the industry chapter.

[2] For the census, a company is defined as a business organization consisting of one establishment or more under common ownership or control.

[3] Industry was defined or redefined for 1972 Census of Manufactures, so data are available only for years shown.

[4] Data for 1967 and 1963 were derived from Table 8, General Statistics for Establishments by Industry Specialization and Primary Product Class Specialization, in vol. II of the 1967 and 1963 Censuses of Manufactures. Separate data for other years are not available.

[5] Data either have associated standard errors exceeding 15 percent or are not consistent with other census series and related data; thus these estimates may be of limited reliability.

[6] Estimate for new capital expenditures has associated standard error of 15 percent or more and may be of limited reliability. Estimates for other data items are of acceptable reliability.

[7] Minimum percentage; exact percentage withheld to avoid disclosing operations of individual companies.

[8] Relationships are not meaningful because of predominance of miscellaneous receipts, particularly receipts for contract and commission work on materials owned by others.

[9] Data in value of shipments column represent value of production rather than value of shipments. Consequently, formula for computing value added by manufacture was modified to exclude any change in finished products inventories between beginning and end of year.

[10] Data in value of shipments column represent value of work done rather than value of shipments. Consequently, formula for computing value added by manufacture was modified to exclude any change in inventories between beginning and end of year.

Table 3a. Summary Statistics for the Industry: 1977

Item	Unit of measure	Gum and wood chemicals (SIC 2861)	Cyclic crudes and intermediates (SIC 2865)	Industrial organic chemicals, n.e.c. (SIC 2869)
Primary product specialization ratio[1]	percent	76	68	89
Coverage ratio[2]	do	67	67	84
All establishments	number	119	191	569
With 1 to 19 employees	do	82	64	223
With 20 to 99 employees	do	24	58	164
With 100 employees or more	do	13	69	182
All employees, average for year	1,000	4.8	35.7	112.3
Payroll for year, all employees	mil. dol.	54.0	631.5	2 108.7
Production workers:				
Average for year	1,000	3.8	23.4	70.7
March	do	3.6	23.5	69.7
May	do	3.9	23.7	70.2
August	do	3.9	23.3	71.5
November	do	3.7	23.1	71.1
Hours	millions	7.8	46.6	145.7
January to March	do	1.8	11.9	35.9
April to June	do	2.0	11.9	38.5
July to September	do	2.0	11.4	34.7
October to December	do	1.9	11.4	36.6
Wages	mil. dol.	38.9	369.8	1 216.5
Cost of materials, etc	do	205.3	3 453.6	13 948.8
Materials, parts, containers, etc., consumed	do	179.6	2 925.0	11 405.5
Resales	do	1.6	113.6	420.5
Fuels consumed	do	18.9	271.8	1 393.9
Purchased electric energy	do	4.7	113.1	452.8
Contract work	do	0.5	30.1	276.0
Value of shipments, including resales	do	301.3	5 637.0	24 232.8
Value of resales	do	3.7	127.2	496.1
Value added by manufacture	do	185.0	2 214.4	10 475.7
Manufacturers' inventories:				
Beginning of year	do	63.6	784.2	2 591.5
Finished products	do	40.6	350.0	1 247.3
Work in process	do	2.3	165.7	474.7
Materials, supplies, fuel, etc	do	20.7	267.7	869.4
End of year	do	65.7	844.4	2 942.7
Finished products	do	40.4	391.7	1 419.7
Work in process	do	1.6	155.8	494.1
Materials, supplies, fuel, etc.	do	23.8	296.9	1 028.9
Capital expenditures for plant and equipment	do	34.7	448.6	3 189.5
New capital expenditures	do	27.0	443.1	3 162.6
New buildings and other structures	do	10.8	52.6	447.7
New machinery and equipment	do	16.2	390.5	2 714.9
Used capital expenditures	do	7.7	5.5	26.9

- Represents zero. (D) Withheld to avoid disclosing operations of individual companies. (NA) Not available. n.e.c. Not elsewhere classified. (S) Withheld because estimate did not meet publication standards. (X) Not applicable. (Z) Less than 50 thousand dollars or hours; under 50 employees.

[1] Represents ratio of primary product shipments to total product shipments (primary and secondary, excluding miscellaneous receipts) for establishments classified in industry.

[2] Represents ratio of primary products shipped by establishments classified in industry to total shipments of such products by all manufacturing establishments, wherever classified.

[3] Relationships are not meaningful because of predominance of miscellaneous receipts, particularly receipts for contract and commission work on materials owned by others.

[4] Minimum percentage; exact percentage withheld to avoid disclosing operations of individual companies.

[5] Data for value of shipments represent value of production rather than value of shipments. Consequently, formula for computing value added by manufacture was modified to exclude any change in finished products inventories between beginning and end of year.

[6] Data for value of shipments represent value of work done rather than value of shipments. Consequently, formula for computing value added by manufacture was modified to exclude any change in inventories between beginning and end of year.

[7] Four-digit industry totals for all items including establishment counts are not equal to sum of 6-digit subindustry figures due to difficulties in classifying a few establishments at subindustry level.

Table 4. Industry Statistics by Employment Size of Establishment: 1977

Industry and employment size class	E[1]	All establishments (no.)	All employees		Production workers			Value added by manufacture (million dollars)	Cost of materials (million dollars)	Value of shipments (million dollars)	New capital expenditures (million dollars)	End-of-year inventories (million dollars)
			Number (1,000)	Payroll (million dollars)	Number (1,000)	Hours (millions)	Wages (million dollars)					
INDUSTRY 2861, GUM AND WOOD CHEMICALS												
Total	-	119	4.8	54.0	3.8	7.8	38.9	186.0	205.3	391.3	27.0	85.7
Establishments with an average of—												
1 to 4 employees	E8	49	0.1	1.0	0.1	0.2	0.7	3.2	4.2	7.4	(7.8)	1.3
5 to 9 employees	E4	15	0.1	1.0	0.1	0.2	0.8	4.1	6.3	10.4	(D)	1.3

- Represents zero. (D) Withheld to avoid disclosing operations of individual companies. Data for this item are included in figures in parentheses above. (NA) Not available. n.e.c. Not elsewhere classified. (S) Withheld because estimate did not meet publication standards. (X) Not applicable. (Z) Less than 50 thousand dollars or hours, under 50 employees.

[1] Payroll and sales data for small single-unit companies with up to 20 employees (cutoff varied by industry) were obtained from administrative records of other government agencies rather than from census report forms. These data were then used in conjunction with industry averages to estimate the balance of items shown for these small establishments. This technique was also used for a small number of other establishments whose reports were not received at time data were tabulated. The following symbols are shown where estimated data based on administrative records data account for 10 percent or more of figures shown: E1—10 to 19 percent; E2—20 to 29 percent; E3—30 to 39 percent; E4—40 to 49 percent; E5—50 to 59 percent; E6—60 to 69 percent; E7—70 to 79 percent; E8—80 to 89 percent; E9—90 to 99 percent; E0—100 percent.

[2] Report forms were not mailed to small single-unit companies with up to 20 employees (cutoff varied by industry). Payroll and sales data for 1977 were obtained from administrative records supplied by other agencies of the Federal Government. These data were then used in conjunction with industry averages to estimate the balance of items shown. Data are also included in respective size classes shown.

[3] Data in value of shipments column represent value of production rather than value of shipments. Consequently, formula for computing value added by manufacture was modified to exclude any change in finished products inventories between beginning and end of year.

[4] Data in value of shipments column represent value of work done rather than value of shipments. Consequently, formula for computing value added by manufacture was modified to exclude any change in inventories between beginning and end of year.

[5] Four-digit industry totals for all items including establishment counts are not equal to sum of 6-digit subindustry figures due to difficulties in classifying a few establishments at subindustry level.

Table 5a. Industry Statistics by Industry and Primary Product Class Specialization: 1977

[Table presents selected statistics for establishments according to their degree of specialization in products primary to their industry. Measures of plant specialization shown are (1) industry specialization ratio of primary product shipments to total product shipments (primary plus secondary, excluding miscellaneous receipts) for the establishment; and (2) product class specialization ratio of largest primary product class shipments to total product shipments (primary plus secondary, excluding miscellaneous receipts) for the establishment. See appendix for method of computing ratios. Statistics for establishments with specialization ratios of less than 75 percent are included in total lines but are not shown as a separate class. In addition, data may not be shown for various reasons; e.g., to avoid disclosing operations of individual companies. For explanation of terms, see appendix A]

Procedures Used to Develop the 1978, 1979, 1980, and Projected 1990 OES Survey-Based Matrices

Introduction

The Bureau of Labor Statistics converted the National industry-occupational matrix from a Census base to an Occupational Employment Statistics (OES) survey base in 1981. This paper presents a brief overview of the general procedures established to develop OES survey-based matrices and describes the detailed steps used to develop the first National matrices based on OES survey data.

In early 1982, a bulletin will be published presenting the 1978 and 1990 matrices. The 1980 and 1990 matrices are the basis of the analytical statements on employment outlook and job openings for the 1982-83 edition of the Occupational Outlook Handbook.

OVERVIEW

Because the OES surveys are conducted on a three-year cycle in which each covered industry is only surveyed once in each cycle, a matrix developed for any given reference year must be based on survey data for three different years. Given this data constraint, a matrix for any given year should most accurately describe occupational employment by industry if it were based on data that were at most one year from the reference year. For example, OES survey data for 1978, 1979, and 1980 should provide the most reliable data to construct a 1979 matrix based on OES survey data.

The timing in which National OES survey data become available and the established cycle for production of National occupational projections and publication of the Occupational Outlook Handbook, however, have resulted in the development of procedures in which matrices are developed for specific reference years prior to the availability of the most reliable data that will become available. Survey data are generally not available until late December of the year following the survey reference year. For example, 1980 OES survey data will not be available until December 1981. Program commitments, however, required that data for 1980 be presented in the Occupational Outlook Handbook that was completed in mid-1981 and which will be published in 1982. Because staffing patterns do not change significantly over a three-year period, procedures were developed in which a preliminary 1980 matrix was developed using the survey data available at the time the employment estimates presented in the Handbook were developed.

The following is a general description of the system that has been designed for developing OES survey-based matrices. Three base year or current matrices will be produced for every reference year. They are to be titled I, Preliminary; II, Revised; and III, Final. The preliminary matrix will be based on OES survey data for the three years prior to the reference year. The revised matrix will be based on OES survey data for the reference year and the two previous years. The final matrix will be based on OES survey data for the reference year, the previous year, and the year following the reference year. The 1979-I matrix, therefore, is based on OES survey data for 1976, 1977, and 1978. The 1979-II matrix uses 1977, 1978, and 1979 survey data. A 1979-III matrix will be constructed using 1978, 1979, and 1980 data after the latter become available in December 1981.

To develop employment data for each reference year's matrix (whether it is a I, II, or III), the staffing patterns from the OES survey data are applied to actual annual average industry employment totals from the Current Employment Survey--CES--(ES-202 data for industries for which CES data are not available) for the reference year. To develop a matrix that covers all workers, the OES survey-based data are supplemented with data for industries not covered by the OES surveys. Estimates of occupational employment of self-employed persons and unpaid family workers are also developed and added at the total all industries level.

DETAILED DESCRIPTION OF PROCEDURES USED TO DEVELOP THE FIRST CURRENT AND PROJECTED NATIONAL OES SURVEY-BASED MATRICES

The first National OES survey-based matrices were developed during 1980 and 1981. Matrices were developed for the years 1978, 1979, 1980, and projected 1990. Current or base year matrices produced include a 1978-II, 1978-III, 1979-I, 1979-II, and a 1980-I. For industries covered by the OES surveys, the 1978-II and 1979-I have the same staffing patterns and the 1978-III, 1979-II, and 1980-I have the same staffing patterns. Staffing patterns for the nonsurveyed sectors and the occupational distribution of self-employed persons and unpaid family workers are the same for the three matrices for each reference year, whether a I, II, or III matrix, because the actual source data for the reference year were available at the time the matrix was developed.

Current Year Matrices (1978, 1979, and 1980)

Industry Controls

In all current years, industry controls for wage and salary workers in the 378 industries in the National survey-based matrices are annual averages. Most of the data are from three-digit SIC industry estimates from CES series; data for railroads, education, Federal government, State government, and local government are on a two-digit SIC basis. Wage and salary workers in all five of the current matrices discussed in this paper use CES estimates benchmarked to ES-202 data in the spring of 1981. These CES data will be published in August 1981 as Supplement to Employment and Earnings Revised Establishment Data.

In some cases, detailed industries are disaggregated from CES series that were combinations of two or more three-digit SIC industries. In these cases, ES-202 data for 1978 were used to disaggregate the 1978 CES data and ES-202 data for 1979 were used to disaggregate the 1979 and 1980 CES data. When the 1980 ES-202 data become available, they will be used to disaggregate the 1980 CES data, where necessary, for the 1980-II matrix. The ES-202 data for 1978 will be published in the fall of 1981 by the National Technical Information Service (NTIS) and comparable data for 1979 will be published by NTIS in early 1982.

In a few cases--agriculture, forestry, and fishing and private households--industry employment controls were obtained from the CPS. These data are published each year in the January issue of Employment and Earnings following the reference year.

1978 Matrices

1978-II Matrix. The 1978-II matrix included data from Occupational Employment Statistics (OES) surveys on wage and salary worker staffing patterns in State government and local government collected in 1975 (no later data were available); transportation, communications, and public utilities industries collected in 1975 and 1976; trade industries, Federal government, hospitals, and railroads collected in 1976; manufacturing industries collected in 1977; and nonmanufacturing industries collected in 1978.

A combined data file of all the OES survey staffing patterns within the scope of the 1978-II matrix was produced and benchmarked to the 1978 industry controls. This benchmarking step was necessary for two reasons: (1) OES survey data represent observations taken in the spring (second quarter) of the survey year, and (2) the combined OES survey file represents observations in different years; benchmarking theoretically unifies the data to a single year. Because of the differences that can occur as a result of benchmarking to annual averages for a single year, different values for any single occupation/industry cell are usually recorded in the matrix and in the actual OES survey. Wage and salary worker staffing patterns for the nonsurveyed industries--agriculture, forestry, and fishing; education; and private households--which were developed from the Census-based matrix and the CPS were also inputed to this combined data file. Details of the development of the estimates for the nonsurveyed sectors are given in a later section of this paper.

Data on employment for some detailed occupations in the OES survey-based matrix are not collected in some OES surveys, generally because employment is believed to be too small to develop reliable survey estimates. Employment in such occupations, however, is included in a broader category in the OES survey, generally in a residual occupation such as "all other professional workers." For many of these occupational cells, a procedure was developed to disaggregate an employment estimate from the appropriate OES survey data based on employment for a similar occupation/industry cell in the Census-based matrix. 1/ For some occupations included in some OES surveys, however, no procedure was believed to be adequate to disaggregate data for industries in which the occupation was not included in the survey. In such cases, available OES survey data were collapsed into the appropriate residual category in the OES survey-based matrix.

In some cases, two or more detailed survey occupations were collapsed into a single occupation that had a Census-based matrix equivalent. In these cases, sufficient information or knowledge was lacking on which to make employment estimates for cells that had not been surveyed and for which analysts felt there should be employment. For other occupations, collapsing survey data to the comparable Census-based matrix occupations enabled analysts to disaggregate employment estimates from the survey-based matrix residuals. In this manner, detailed employment information for a number of specialized kinds of compositors, collected only in the printing industry, was suppressed to the broad title of compositors, which was then disaggregated from the residual all other crafts workers for the missing cells. 2/

Once the wage and salary worker portion of the matrix had been developed, the matrix was listed off in two forms: industry by occupation and occupation by industry (transposed matrix). Staff analysts examined the data to identify cells that were inconsistent with their knowledge about an industry or an occupation. The analysis concentrated on occupation/industry cells for which employment estimates were developed by disaggregation procedures.

For some occupations, analysts who reviewed the matrix believed that employment did exist in industries that showed no employment and recommended that employment be added for these matrix cells. To implement these recommendations necessitated further disaggregation of survey-based matrix residuals. Frequently, more than one occupation had to be disaggregated from the same residual to account for the recommendations. In these cases, three policies were generally followed before the changes in the matrix were made. (1) If the sum of the recommended changes did not exceed the appropriate residual, the changes were accepted. (2) If the sum of the recommended changes did exceed the appropriate residual, the recommendations were prorated so that each cell recommended for change received a portion of the residual. (3) If the designated residual contained no employment, updates were disallowed. One notable exception was made to the latter procedure for data processing machine mechanics. For this occupation, employment estimates were disaggregated, to the limits of the residuals, from all other mechanics, all other engineering technicians, and all other technicians, because it was believed that these workers could have been included in all three categories in the OES surveys.

A very detailed procedure was followed to review all update recommendations received from the analytical staff. Recommendations that were accepted were incorporated manually into the matrix. Appropriate residuals were manually adjusted. A total of 4,776 manual updates were made (including updates to residuals). Most updates (about two-thirds) were less than 50 persons in size. 3/

The final step in developing the current employment estimates was to add the separately developed estimates of self-employed persons and unpaid family workers to the updated matrix by detailed occupation at the total all industries level. Details of the methods used to develop these estimates are contained in a later section of this paper.

1978-III Matrix. This matrix and the 1979-II have the same staffing patterns. The detailed occupational employment values are different only because of the different industry controls used in the two years. A detailed explanation of the development of the staffing patterns for the 1978-III matrix is given below in the section discussing the 1979-II matrix.

1979 Matrices

1979-I Matrix. This matrix was developed by first replacing the detailed wage and salary worker occupational employment data for the nonsurveyed sectors with 1979 estimates and then applying the 1979 industry controls to those industries in the 1978-II matrix where wage and salary worker staffing patterns were based on OES survey data. Detailed occupational employment estimates of self-employed persons and unpaid family workers were prepared for 1979. Because the 1979-II matrix was prepared immediately after the 1979-I matrix, the 1979-I was not used for any substanative analysis.

1979-II Matrix. This matrix, which has the same staffing patterns as the 1978-III matrix, includes data from OES surveys of hospitals and railroads collected in 1976 (no later data were available), manufacturing industries and Federal government collected in 1977, nonmanufacturing industries collected in 1978, and balance of nonmanufacturing industries collected in 1979. 4/ Balance of nonmanufacturing was a new designation in 1979, resulting from the combination of surveys, some of which had been conducted in 1975 and others in 1976. Included are transportation, communication, and public utilities; wholesale and retail trade; State government; and local government. Although a survey of employment in educational services establishments was conducted for the first time in 1979, summary data were not available at the time that matrix production began. Consequently, employment estimates for education were developed at the National level from secondary sources, as explained in a later section of this paper.

Estimates from the 1977 and 1978 OES surveys, along with estimates from the 1975 and 1976 OES surveys, had previously been used to build the 1978-II National survey-based matrix. The simplest method of producing the 1979-II matrix was to replace the 1975 and 1976 data with 1979 data for the same industries, leaving the 1977 and 1978 surveyed industry staffing patterns intact. Twenty-four new occupations, 12 of which were in the education survey, that were added for the 1979 round of surveys, were collapsed back to the appropriate survey occupations that appeared in the 1975 and 1976 rounds. In order to duplicate the matrix parameter file, these collapses were done on an industry by industry basis The application of 1979 industry annual averages from the CES benchmarked all sectors to 1979 employment.

Since the 1978-II matrix that was used in this procedure had already been updated, only the new 1979 estimates were reviewed and updated. The basis for these updates to the new survey data was the updates for the same cells in the 1978-II matrix. Similar values were used, to the limit of the appropriate residuals. Manual calculations of the affected residuals were incorporated also.

Employment estimates for 1979 for the nonsurveyed sectors of agriculture, forestry, and fishing, education, and private households were developed and added. Occupational employment estimates for self-employed persons and unpaid family workers at the all industries level (the same as in the 1979-I matrix) were added to the matrix.

The wage and salary worker portion of this 1979-II matrix for OES survey covered industries was benchmarked to 1978 annual average industry controls from the CES to produce the 1978-III matrix. Nonsurveyed sectors and self-employed persons and unpaid family workers for 1978 were added. The 1978-III matrix became the base year for the 1990 projected matrix.

1980 Matrix

1980-I Matrix. As for the 1979-I matrix, the 1980-I matrix was developed by replacing the detailed occupational employment data for the nonsurveyed sectors of agriculture, forestry, fishing, education, and private households with 1980 employment estimates that had been developed separately from CPS data. The 1980 annual average industry controls from the CES for wage and salary workers were used to benchmark the staffing patterns from the 1979-II matrix to preliminary 1980 staffing patterns. Detailed 1980 occupational employment estimates of self-employed persons and unpaid family workers, developed separately, were added. Thus, the wage and salary worker staffing patterns in the 1978-III, 1979-II, and 1980-I matrices are the same, having been based on the same set of OES survey rounds.

Employment estimates from the 1980-I matrix will be used in the 1982-83 edition of the Occupational Outlook Handbook.

Nonsurveyed Sectors

Occupational employment estimates within industry sectors not covered by OES survey data--agriculture, forestry, and fishing; education; and private households--were developed at the 2-digit industry level and incorporated into the matrix estimating system as data files, just as if they had been surveyed. 5/ The primary inputs in developing these estimates were the CPS and the 1978 National Census-based matrix.

Agriculture. Staffing patterns for agriculture, forestry, and fishing are based on patterns for private wage and salary workers in the Census-based matrix and the CPS. Using the private wage and salary worker patterns eliminated the double-counting of Federal, State, and local government workers employed in these industries, who were already counted in the detailed government industries.

Data from the 1978 Census-based matrix industry, agricultural production, was on a 1967 SIC basis. To use these data in the OES survey-based matrix, which is on a 1972 SIC basis, the Census-based matrix data was divided into the two detailed survey-based matrix industries agricultural production, crops, and agricultural production, livestock. This distribution was made on a 70/30 basis, as a result of discussions held with officials of the Department of Agriculture. All survey-based matrices for the years 1978-1980 reflect this percentage distribution. The staffing pattern in the 1978 Census-based matrix industry, agricultural production, was used for both OES survey-based matrix industries, except for an adjustment to the total employment of athletes in the two survey-based matrix industries to reflect the 80 percent of total athletes in agriculture in the Census-based matrix who were assumed to be horse trainers in the survey-based matrix industry, agricultural production, livestock. An 80/20 adjustment also was made to the control value from the Census-based matrix value for veterinarians to reflect the greater proportion of these workers who would be expected to be found in agricultural production, livestock. After these adjustments, all other cells were forced to the control totals from the CPS for farm workers and for total wage and salary workers for all detailed agriculture, forestry, and fishing industries.

Educational Services. Occupational employment estimates in the educational services sector were based on the 1978 Census-based matrix staffing pattern for all wage and salary workers, including private industry and Federal, State, and local government workers. 6/ Government workers were included in this industry because of their significance to total education employment and because of the need to generate employment estimates for education separate from the much larger employment estimates for the government sectors. In these matrices, education workers are not included in the estimates for State and local government. A few further disaggregations of occupations were made based on limited data from one State's OES survey in 1976. 7/ These occupations were refined using ratios from that survey and included college teachers, graduate students, and extension service specialists from college and university teachers; librarians and audio-visual specialists from librarians; three kinds of file clerks; four kinds of food service workers; and a number of other detailed survey occupations, a complete list of which is shown below.

Based on information available from the National Center for Educational Statistics (NCES) and other secondary sources, five cells were fixed in the 1978 matrices: Elementary school teachers; technical assistants, library; janitors; secretaries; and typists. All other cells in the educational services sector were forced to the 1978 industry control. The 1978 pattern was used to developed the 1979 and 1980 estimates.

Private Households. For each year's OES survey-based matrix, the CPS annual average employment for each of the five detailed private household worker occupations was used as a fixed cell. The remaining occupations in the private household industry were developed by forcing the remainder of the CPS annual average industry employment into a distribution based on the private household industry in the 1978 Census-based matrix.

With the addition of the nonsurveyed sectors to the surveyed sectors, total wage and salary worker matrices were produced, by occupation and industry.

Self-Employed Persons and Unpaid Family Workers

Estimates of occupational employment of self-employed persons and unpaid family workers were developed only at the total all industries level, rather than by detailed industry as in the Census-based matrix, because the development of such data would have produced very unreliable estimates. The general procedure was to develop employment estimates of self-employed persons and unpaid family workers for each detailed Census-based matrix occupation and then distribute the employment to related OES survey-based matrix occupations.

The 1978 Census-based matrix was the primary source of data used to develop estimates of self-employed persons and unpaid family workers. Data in the 1978 Census-based matrix, however, were modified for some occupations where the relationship of self-employed persons and unpaid family workers to total employment were out of line with trends over the 1971-78 period, based on CPS data. To develop estimates for 1979 and 1980, trends in the relationship of self-employed persons and unpaid family workers to total employment over the 1971-80 period were used to modify the 1978 ratios. These ratios were applied to CPS total employment for each occupation in these years to develop estimates of self-employed persons and unpaid family workers. The resulting data were forced to agree with the CPS 1979 and 1980 annual average employment estimates for each class of worker.

The employment totals for self-employed persons and unpaid family workers in each Census-based matrix occupation were distributed to OES survey-based matrix occupations. A list of OES survey-based matrix occupations that were related to the 400 Census-based matrix occupations was developed. Analysts studied these relationships and distributed the Census-based matrix occupational control totals to OES survey-based matrix occupations. Some occupations were a one-for-one match. For other occupations, however, a distribution was made based on limited information. One of the following procedures was used by individuals making the estimates for each occupation: (1) The entire Census-based matrix employment of self-employed persons and unpaid family workers was distributed to related OES survey-based matrix occupations based on the distribution of wage and salary workers in those ocupations in the OES survey-based matrix; (2) The entire Census-based matrix employment for each class of worker was distributed on a judgment basis to selected OES survey-based matrix occupations to which it was related; (3) The entire Census-based matrix employment of self-employed persons and unpaid family workers was placed in an appropriate OES survey-based matrix occupational residual; and (4) Any combination of the above that made sense in terms of the analyst's knowledge of the specific occupation(s).

In using these procedures, the analysis was focused on the 1978 data and then similar procedures were used for 1979 and 1980 for each occupation. In general, the most common procedure followed was to distribute the control totals for self-employed persons and unpaid family workers in the Census-based matrix by the distribution of wage and salary workers in related OES survey-based matrix occupations. Adjustments were made in cases where this distribution did not make analytical sense. For example, no estimate was made for self-employed judges or self-employed claims takers for unemployment insurance benefits, even if the Census-based matrix occupation where these workers were included had some self-employed persons.

Summary Tables

After employment estimates of self-employed persons and unpaid family workers were developed, they were added to the wage and salary worker employment estimates to produce total employment by occupation at the total all industries level.

Projected Year Matrices (1990)

The 1990 occupational projections were developed as part of the Bureau's economic and employment projections efforts, which include projections of the labor force, gross national product, productivity, industry output, and industry employment. The Bureau developed three alternative 1990 projections, each based on different assumptions concerning such factors as labor force growth, defense expenditures, unemployment rate, and productivity trends. The assumptions and related projections are published in the August 1981 issue of the Monthly Labor Review.

The basic procedure used to develop occupational projections was to apply projected staffing patterns for each industry in the OES survey-based matrix to projected wage and salary worker employment in the related industry. Separate totals for self-employed persons and unpaid family workers were projected for each occupation. These totals were added to the projected wage and salary worker totals for the occupation to develop the total employment projection by occupation. Projections were developed for each of the three alternative scenarios, but the same staffing patterns of industries were used in each alternative. The following detailed procedures were used to develop the occupational projections.

Industry Controls

The Bureau's model produces projections for 156 industry groups. These projections were disaggregated to the 378 industries included in the OES survey-based matrix. In general, projections of industry employment for all CES published series developed through regression analysis were used to disaggregate employment in the 156 sectors. Industry employment projections for the unpublished CES series were developed by disaggregation of the appropriate projected CES series on the basis of trends in ES-202 data.

Occupational Staffing Patterns

Surveyed Sectors. In projecting occupational staffing patterns for industries in previous projection cycles, Decennial Census data were extrapolated into the future based on decade to decade changes. Considerable analysis and review identified the factors that caused changes in staffing patterns. The analysis resulted in many changes to the mechanically developed extrapolated ratios. However, a review of the 1975 occupational projections, done just prior to the development of the most recent 1990 projections, indicated that the major cause of errors in the projections was incorrect projection of occupational ratios. An intensive effort was devoted to research on methods of projecting OES survey-based matrix staffing patterns. 8/

In general, the research tested the merits of a variety of extrapolation techniques. In these tests, use of current staffing patterns in the projected years generally produced better results, on the average, than any extrapolation technique. However, for large occupations that were not affected by any problems related to changes in industry or occupational definitions, the exponential extrapolation technique generally outperformed the constant ratio method. Since the tests were performed on data covering a short period of time and the exponential method worked well for large occupations representing a very significant proportion of employment, this technique was used where possible. The research also indicated that ratios developed through mechanical means must undergo intensive analytical review.

The first step in developing the projected staffing patterns for the OES survey-based matrix was to project trends in OES survey data from the last two OES survey rounds for each industry. Unfortunately, because of changes between survey rounds in industry definitions (change from the 1967 SIC to the 1972 SIC), occupational definitions, survey forms, and geographical coverage, many difficulties were encountered in this process.

Periodically, the SIC system, used as the basis for OES survey industry definitions, is changed. Such a change occurred between the OES survey round providing data for the current 1978 and 1980 matrices and the OES survey round immediately preceeding that affected several industries. As a result, trends could not be developed because the data were not comparable. In these cases, ratios were held constant at 1978 levels for the initial 1990 projected matrix. Trends were extrapolated only in industries in which 95 percent or more of employment included in the 1972 SIC industry definition was also included in the same industry in the 1967 SIC industry definition.

Between the last two survey rounds, definitions were changed for several OES survey occupational categories. Some new occupations were added in the last survey round. With only one observation, trends could not be developed for these new occupations. Additionally, the occupational category that probably included the occupation in the previous round could not be projected because of inconsistent occupational content. Similar situations resulted when occupations were dropped or combined with other occupations in the OES survey.

Even though the OES survey has been conducted since 1971 as a Federal-State cooperative program, all States do not participate in the program and the number of States in each OES survey round has varied. Beginning with the 1977 OES survey, the BLS surveyed the nonparticipating States as a whole and National data became available. 9/ Because National data were not available for both of the last two survey rounds in any industry, data from States that participated in both of the last two OES surveys for each industry were summed and used as a proxy for National data. The number of States providing data used in developing trends to 1990 was as follows for each survey round: 1974 and 1977 manufacturing, 27; 1975 and 1978 nonmanufacturing, 29; and 1973 and 1976 trade, 19. The development of trends, therefore, excluded some States that may have had significant employment in a specific occupation. In future projection rounds, this weakness will be eliminated; National data will become available for two points in time beginning with the 1980 OES survey, except for education and railroads.

To overcome the problems identified above concerning the comparability of OES survey data in the last two OES survey rounds, only those occupations with consistent definitions that were found in industries with consistent SIC content were projected through the exponential extrapolation technique to 1990. The projected trends in survey occupations were related to appropriate OES survey-based matrix occupations. Adjustments were made to these cells and any other cells in the matrix by analysts who reviewed the data for all industries. The analysis was concentrated, however, on industries that employed over 100,000 workers. Cells that were not projected were held constant in 1990 at the 1978 levels. An iteration procedure forced the distribution patterns in each industry to add to 100 percent. These patterns became the initial 1990 projected staffing patterns.

The initial projected staffing pattern in each industry was applied to projected industry employment totals for wage and salary workers to develop the preliminary 1990 occupational projections. These projections were analyzed in detail over a six month period, based on studies of occupations and industries conducted during preparation of the Occupational Outlook Handbook. Factors considered by analysts included changes in production methods, technological changes affecting occupational mix, changes in product mix of industries, changes in average size of establishments in industries, and other economic factors affecting specific occupations.

In addition, some occupations were projected independently of the matrix based on the relationship of the occupation to more closely associated variables. For example, projections of elementary school teachers were based on estimates of the school age population and pupil-teacher ratios. Projections developed in this manner were used in the matrix and adjustments in the ratios for other occupations were made when necessary.

During the analysis, relationships were established between occupations in the Census-based matrix and the OES survey-based matrix to obtain the benefit of a longer time series. Based on all the analyses described above, changes were made in the initial projected OES survey-based matrix and an iteration procedure assured that the staffing pattern in each industry added to 100 percent. The resulting ratios were applied to total projected employment of wage and salary workers in each industry to develop the final occupational projections of wage and salary workers.

Nonsurveyed Sectors. The initial projected 1990 occupational ratios for the agriculture, forestry, and fishing, education, and private households industries were taken directly from the 1990 Census-based matrix developed by the Bureau for 1978-90. The ratios were analysed based on CPS data that became available after the Census-based matrix was developed, and a few ratios were adjusted. The occupational distribution in the Census-based matrix was converted to the OES survey-based matrix distribution in the same way described above for the current year matrices.

The projected ratios were applied to the 1990 industry projections for the appropriate industries. The results were reviewed in detail. Changes in the staffing patterns resulted from this review were incorporated in the final matrix.

Self-Employed Persons and Unpaid Family Workers. Based on an analysis of the trends in the 1978-90 Census-based matrix and the 1971-80 CPS data on the ratio of self-employed persons and unpaid family workers to total employment in each occupation, estimates were developed of the percentage of each of these two classes of workers to total employment in each Census-based matrix occupation. These ratios were applied to projected 1990 total employment for each Census-based matrix occupation. The summed result was compared to the 1990 control totals for these two classes of workers, which had been independently projected as part of the Bureau's economic model. Minor adjustments forced the ratios to 100 percent and the individual estimates to the control totals.

Using the methods already indicated, the Census-based matrix occupational estimates were disaggregated by *Handbook* analysts to the full list of survey-based matrix occupations. These were reviewed for consistency with information developed in the course of other occupational research and appropriate changes were made.

Total Occupational Employment. To develop total employment projections by occupation, projections of wage and salary workers in the surveyed and nonsurveyed sectors was added to the projected totals of self-employed persons and unpaid family workers. Unlike previous projections of total National employment, the totals in the OES survey-based matrix represent the number of jobs by occupation, not the number of persons employed by occupation. 10/ These totals are different because one person may have more than one job. The difference between the number of jobs and the number of persons employed in 1990 is estimated at approximately 7 percent.

Footnotes

1/ For a more detailed explanation of these disaggregation techniques, see "Development of the State OES Survey-Based Matrix," OES Matrix/Projections Memo No. 12, September 10, 1979. Approximately 4 percent of total occupational employment was developed through disaggregation of residuals.

2/ A total of 1,836 detailed survey occupations were used directly, disaggregated, or collapsed to a final occupational list (after manual updating) containing 1,615 detailed matrix occupations. This same final occupational list was used for all 1978, 1979, and 1980 matrices. These numbers may change in future matrices as the number of OES survey occupations included increases or decreases.

3/ A list of these updates was given to States engaged in developing projections for the interim projections project to use as a guide for updating State matrices. In this list, updates of less that 50 persons were excluded to eliminate possible problems in allocating small numbers among the various States. When these smaller updates were removed from the list, the number of updates dropped to 1,543.

4/ Employment in hospitals was resurveyed in 1980. Employment in railroads has not been surveyed since 1976; there are no immediately plans to resurvey this industry.

5/ Although an OES survey of employment in educational services was conducted in 1979, National data from this survey are not available because 10 States did not participate, one of which was California. Furthermore, a combined estimates file of the 41 States that did participate in the OES education survey was not available in time to use in these first National OES survey-based matrices. Surrogate National estimates, based on data from the 41 States, will be used in the 1980-II matrix.

6/ See ftn. 5.

7/ In 1976, Oklahoma became the first State to collect data on employment in educational services. No other data on employment in education were available at the time the matrices discussed in this paper were developed.

8/ For a more detailed explanation, see "Projected Occupational Staffing Patterns of Industries," BLS technical paper, April 1981.

9/ Funds to do this work were provided to the Bureau by the National Science Foundation.

10/ Wage and salary workers in agriculture, private households, and education were only counted once, even if they held more than one job because the CPS was the source of data on employment in these industries. Similarly, self-employed persons and unpaid family workers are counted only once in their primary job.
